ON A NEW METHOD IN ELEMENTARY NUMBER THEORY WHICH LEADS TO AN ELEMENTARY PROOF OF THE PRIME: NUMBER THEOREM

By P. Erdös
Department of Mathematics, Syracuse University
Communicated by P. A. Smith, April 16, 1949

1. Introduction.-In the course of several important researches in elementary number theory A. Selberg ${ }^{1}$ proved some months ago the following asymptotic formula:

$$
\begin{equation*}
\sum_{p \leqq x}(\log p)^{2}+\sum_{p q \leqq x} \log p \log q=2 x \log x+O(x) \tag{1}
\end{equation*}
$$

where $p$ and $q$ run over the primes. This is of course an immediate consequence of the prime number theorem. The point is that Selberg's in-
genious proof of (1) is completely elementary. Thus (1) can be used as a starting point for elementary proofs of various theorems in analytical number theory, which previously seemed inaccessible by elementary methods.

Using (1) I proved that $p_{n+1} / p_{n} \rightarrow 1$ as $n \rightarrow \infty$. In fact, I proved the following slightly stronger result: To every $c$ there exists a positive $\delta(c)$, so that for $x$ sufficiently large we have

$$
\begin{equation*}
\pi[x(1+c)]-\pi(x)>\delta(c) x / \log x \tag{2}
\end{equation*}
$$

where $\pi(x)$ is the number at primes not exceeding $x$.
I communicated this proof of (2) to Selberg, who, two days later, using (1), (2) and the ideas of the proof of (2), deduced the prime number theorem

$$
\begin{align*}
\lim _{x \rightarrow \infty} \frac{\pi(x) \log x}{x}= & 1 \text { or, equivalently }{ }^{2} \\
& \lim _{x \rightarrow \infty} \frac{\vartheta(x)}{x}=1, \text { where } \vartheta(x)=\sum_{p \leqq x} \log p . \tag{3}
\end{align*}
$$

In a few more days, Selberg simplified my proof of (2), and later we jointly simplified the proof of the prime number theorem. The new proof no longer required (2), but used the same ideas as in the proof of (2) and (3). I was also able to prove the prime number theorem for arithmetic progressions. My proof of the latter was helped by discussions with Selberg and it utilizes ideas of Selberg's previous elementary proof of Dirichlet's theorem, ${ }^{3}$ according to which every arithmetic progression whose first term and difference are relatively prime contains infinitely many primes. This proof will be given in a separate paper.

Selberg has now a more direct proof of (3), which is not yet published. It is possible, therefore, that the present method may prove to be only of historical interest.

I now proceed to give the proofs as they occurred in chronological order. (It should be remarked that we never utilize the full strength of (1), indeed an error term $o(x \log x)$ is all that is used in the following proofs.)

We introduce the following notation:

$$
A=\limsup _{x \rightarrow \infty} \frac{\vartheta(x)}{x}, a=\liminf _{x \rightarrow \infty} \frac{\vartheta(x)}{x} .
$$

First, we state a few elementary facts about primes which will be used subsequently. Of these, I, II and IV are well known in elementary prime number theory, while III is shown to be a simple consequence of (1).
I. $a>0$.
II. $\sum_{p \leqq x} \frac{\log p}{p}=[1+o(1)] \log x$.
III. Let $x_{2}>x_{1}$. Then

$$
\vartheta\left(x_{2}\right)-\vartheta\left(x_{1}\right)<2\left(x_{2}-x_{1}\right)+o\left(x_{2}\right) .
$$

Thus, in particular, if $x_{1}=0$, we obtain $A \leqq 2$.
Put in (1) $x=x_{2}$ and $x=x_{1}$ and subtract. Then we obtain

$$
\begin{array}{r}
\sum_{x_{1}<p \leqq x_{2}}(\log p)^{2} \leqq 2 x_{2} \log x_{2}-2 x_{1} \log x_{1}+o\left(x_{2} \log x_{2}\right) \leqq \\
2\left(x_{2}-x_{1}\right) \log x_{2}+o\left(x_{2} \log x_{2}\right) . \tag{4}
\end{array}
$$

We distinguish two cases: (A) $x_{1} \geqq x_{2} /\left(\log x_{2}\right)^{2}$. Then clearly $\log x_{1}=$ $(1+o(1)) \log x_{2}$ and III follows from (4) on dividing both sides by $\log x_{2}$. (B) $x_{1}<x_{2} /\left(\log x_{2}\right)^{2}$. Then we have by (A)

$$
\begin{aligned}
& \vartheta\left(x_{2}\right)-\vartheta\left(x_{1}\right)<\vartheta\left(x_{2}\right)-\vartheta\left(x_{2} /\left(\log x_{2}\right)^{2}\right)+\frac{x_{2}}{\left(\log x_{2}\right)^{2}} \log x_{2}< \\
& \quad 2\left(x_{2}-\frac{x_{2}}{\left(\log x_{2}\right)^{2}}\right)+o\left(x_{2}\right)=2\left(x_{2}-x_{1}\right)+o\left(x_{2}\right), \text { q. e. d. }
\end{aligned}
$$

IV. $A \leqq 1.5$. This is a consequence of the known result $\vartheta(x) \leqq 1.5 x$.
2. Proof of (2).-It is equivalent to prove that to every positive $c$ there exists a positive $\delta(c)$ such that $\vartheta[(1+c) x]-\vartheta(x)>\delta(c) x$ for $x$ sufficiently large.

Suppose this not true, then there exist positive constants $c^{\prime}$ and corresponding arbitrarily large $x$ so that

$$
\begin{equation*}
\vartheta\left[x\left(1+c^{\prime}\right)\right]-\vartheta(x)=o(x) . \tag{5}
\end{equation*}
$$

Put $C=\sup c^{\prime}$. It easily follows from I and the finiteness of $A$ that $C<\infty$.

First we show that $C$ satisfies (5), in other words, that there are arbitrarily large values of $x$ for which

$$
\begin{equation*}
\vartheta[x(1+C)]-\vartheta(x)=o(x) . \tag{6}
\end{equation*}
$$

Choose $c^{\prime}>C-1 / 2 \epsilon$ and let $x \rightarrow \infty$ through values satisfying (5). Then by III we have

$$
\begin{array}{r}
\vartheta[x(1+C)]-\vartheta(x)=\vartheta[x(1+C)]-\vartheta\left[x\left(1+c^{\prime}\right)\right]+\vartheta\left[x\left(1+c^{\prime}\right)\right]- \\
\vartheta(x) \leqq 2\left(C-c^{\prime}\right) x+o(x)<\epsilon x+o(x)
\end{array}
$$

which (since $\epsilon$ can be chosen arbitrarily small) proves (6).
Now we shall show that (6) leads to a contradiction. From (1) we obtain by subtraction
$\sum_{x<p \leqq x(1+C)}(\log p)^{2}+\sum_{x<p q \leqq x(1+C)} \log p \log q=2 C x \log x+o(x \log x)$.
From (6) we have for suitable $x$ since $\sum_{x<p \leqq x(1+c)}(\log p)^{2}=o(x \log x)$
$\sum_{p \leqq x(1+\boldsymbol{C})} \log p\left(\vartheta\left[\frac{x}{p}(1+C)\right]-\vartheta\left(\frac{x}{p}\right)\right)=2 C x \log x+o(x \log x)$
Now we deduce the following fundamental lemma.
Lemma 1. Let $x \rightarrow \infty$ through values satisfying (6), then for all primes $p \leqq x(1+C)$, except possibly for a set of primes for which

$$
\begin{equation*}
\sum \frac{\log p}{p}=o(\log x) \tag{8}
\end{equation*}
$$

we have

$$
\begin{equation*}
\vartheta\left[\frac{x}{p}(1+C)\right]-\vartheta\left(\frac{x}{p}\right)=2 C_{-}^{x}+o\left(\frac{x}{p}\right) . \tag{9}
\end{equation*}
$$

Suppose the lemma is not true. Then there exist two positive constants $b_{1}$ and $b_{2}$ so that for arbitrarily large $x$ (satisfying (6)) we have for a set of primes satisfying $\sum_{p \leqq x(1+c)} \frac{\log p}{p} \sim b_{1} \log x$

$$
\begin{equation*}
\vartheta\left[\frac{x}{p}(1+C)\right]-v\left(\frac{x}{p}\right)<\left(2 C-b_{2}\right) \frac{x}{p} \tag{10}
\end{equation*}
$$

But then from II, III and (10), since (9) holds at best for a set of primes satisfying $\sum \frac{\log \boldsymbol{p}}{\boldsymbol{p}} \sim\left(1-b_{1}\right) \log x$ we have
$\sum_{p \leqq x(1+C)} \log p\left(\vartheta\left[\frac{x}{p}(1+C)\right]-\vartheta\binom{\boldsymbol{x}}{\boldsymbol{p}} \leqq b_{1}\left(2 C-b_{2}\right) x \log x+\right.$

$$
2 C\left(1-b_{1}\right) x \log x+o(x \log x)=\left(2 C-b_{1} b_{2}\right) x \log x+o(x \log x)
$$

But this contradicts (7), hence the lemma is established.
The primes satisfying (9) we shall call good primes, the other primes we shall call bad primes (of course the goodness and badness of a prime depends on $x$ ).

We shall prove the existence of a sequence of good primes $p_{1}<p_{2}<\ldots p_{k}$ satisfying the following conditions:

$$
\begin{align*}
10 p_{1}<p_{k}<100 p_{1},(1+C)(1+t)^{2} p_{i}>p_{t+1} & > \\
(1+t) p_{i}, i & =1,2, \ldots, k-1 \tag{11}
\end{align*}
$$

where $t$ is a small but fixed number (small compared to $C$ ). Since $(1+t)^{k}<100$ it is clear that $k<k_{o}$ with constant $k_{o}=k_{o}(t)$.

Suppose we already established the existence of a sequence satisfying (11). Then we prove (2) as follows: Consider the two intervals

$$
\begin{equation*}
\left[\frac{x}{p_{i}+1}, \frac{x}{p_{i+1}}(1+C)\right],\left[\frac{x}{p_{i}}, \frac{x}{p_{i}}(1+C)\right] \tag{12}
\end{equation*}
$$

If they overlap, then by (11)

$$
\frac{x}{p_{i+1}}(1+t)<\frac{x}{p_{i}}<\frac{x}{p_{i+1}}(1+C)
$$

Clearly

$$
\begin{equation*}
\vartheta\left(\frac{x}{p_{i}}\right)-\vartheta\left(\frac{x}{p_{i+1}}\right)=2\left(\frac{x}{p_{i}}-\frac{x}{p_{i}+1}\right)+o\left(\frac{x}{p_{i}}\right) \tag{13}
\end{equation*}
$$

since otherwise

$$
\vartheta\left(\frac{x}{p_{i}}\right)-\vartheta\left(\frac{x}{p_{i+1}}\right)<\left(2-c_{1}\right)\left(\frac{x}{p_{i}}-\frac{x}{p_{i}+1}\right)
$$

with $c_{1}>0$ and we would have from (9)

$$
\vartheta\left[\frac{x}{p_{i+1}}(1+C)\right]-\vartheta\left(\frac{x}{p_{i}}\right)>\left(2+c_{2}\right)\left[\frac{x}{p_{i+1}}(1+C)-\frac{x}{p_{i}}\right]
$$

which contradicts III. Adding (13) and (9) with $p=p_{i}$ we obtain

$$
\begin{equation*}
\vartheta\left[\frac{x}{p_{i}}(1+C)\right]-\vartheta\left(\frac{x}{p_{i}+1}\right)=2\left[\frac{x}{p_{i}}(1+C)\right]-\frac{x}{p_{i+1}}+o\left(\frac{x}{p_{i}}\right) \tag{14}
\end{equation*}
$$

If the intervals (12) do not overlap we obtain by a simple calculation (using (9) and the fact that $t$ is small)

$$
\begin{equation*}
\vartheta\left[\frac{x}{p_{i}}(1+C)\right]-\vartheta\left(\frac{x}{p_{i+1}}\right)>1.9\left[\frac{x(1+C)}{p_{i}}-\frac{x}{p_{i+1}}\right] \tag{15}
\end{equation*}
$$

Adding all the equations (14) and (15) (for $i=1,2, \ldots, k$ ) we clearly obtain

$$
\begin{equation*}
\vartheta\left[\frac{x}{p_{1}}(1+C)\right]-\vartheta\left(\frac{x}{p_{k}}\right)>1.9\left[\frac{x}{p_{1}}(1+C)-\frac{x}{p_{k}}\right] \tag{16}
\end{equation*}
$$

Since $p_{k}>10 p_{1}$ we obtain from (16)

$$
\begin{equation*}
\vartheta\left[\frac{x}{p_{1}}(1+C)\right]>1.6 \frac{x}{p_{1}}(1+C) . \tag{17}
\end{equation*}
$$

But (17) contradicts IV.
Thus to complete the proof of (2) it will suffice to show the existence of a sequence of good primes satisfying (11).

Consider the intervals

$$
I_{r}=\left(B^{2 r}, B^{2 r+1}\right), r=0,1, \ldots,\left[\frac{\log x}{2 \log B}\right]-1,
$$

where $B$ is a fixed, sufficiently large number. Clearly all the intervals $I_{r}$ lie in the interval $(0, x)$. First we show that with the exception of $\&$ $\boldsymbol{\sigma}(\log x) r$ 's the interval $I_{r}$ contains good primes. From I and IV it easily follows that for sufficiently large $B$ we have (since $\vartheta(B x)-\vartheta(x)>c x$ )

$$
\sum_{p \text { in } I_{r}} \frac{\log p}{p}>c_{1}\left(c_{1}>0 \text { independent of } r\right)
$$

Thus if there were $c_{2} \log x$ with $c_{2}>0$ of the $I_{r}$ 's without good primes, we would have

$$
\sum_{p \text { bad }} \frac{\log p}{p}>c_{1} c_{2} \log x
$$

which contradicts (8).
Let now $p_{1}^{(r)}$ be the smallest good prime in (if it exists), and suppose that a sequence $p_{1}^{(r)}, p_{2}^{(r)}, \ldots, p_{i}^{(r)}$ satisfying (11) exists, but no $p_{i+1}^{(r)}$ satisfying (11) can be found. Thus, all the primes in

$$
J_{i}^{(r)}=\left[p_{i}^{(r)}(1+t), p_{i}^{(r)}(1+t)^{2}(1+C)\right]
$$

are bad. We have, by the definition of $C$,

$$
\sum_{p \text { in } J^{(r)}} \log p>\eta p_{i}^{(r)}(1+t)^{2}(1+C),(\eta \text { absolute constant }) .
$$

Thus

$$
\begin{equation*}
\sum_{p \text { in } J^{(r)}} \frac{\log p}{p}>\eta \tag{18}
\end{equation*}
$$

Clearly for $B>100$ we have $p_{i}^{(r)}(1+t)^{2}(1+C)<B^{2 r+2}$. Thus the intervals $J_{i_{1}}{ }^{r_{1}}, J_{i_{2}}{ }^{r_{2}}, \ldots$ do not overlap. Hence from (18), since the number of $r$ 's with $p_{1}{ }^{(r)}$ existing is $>\frac{\log x}{4 \log B}$,

$$
\sum_{p \text { bad }} \frac{\log p}{p}>\frac{\eta \log x}{4 \log B}
$$

which contradicts (8) and establishes (2).
3. Selberg's deduction of the prime number theorem from (2).—Assume $a<A$. First we prove the following lemmas.

Lemma 2. $a+A=2$.
Choose $x \rightarrow \infty$ so that $\vartheta(x)=A x+o(x)$. Then a simple computation (as in the proof of III) shows that

$$
\sum_{p \leqq x}(\log p)^{2}=A x \log x+o(x \log x) .
$$

Thus from (1)

$$
\begin{equation*}
\sum_{p \leqq x}(\log p) \vartheta\left(\frac{x}{p}\right)=(2-A) x \log x+o(x \log x) \tag{19}
\end{equation*}
$$

By the definition of $a$ and by II we obtain by a simple computation

$$
\sum_{p \leqq x}(\log p) \vartheta\left(\frac{x}{p}\right) \geqq a x \sum_{p \leqq x} \frac{\log p}{p}+o(x \log x)=a x \log x+o(x \log x)
$$

Thus from (19), $2 \geqq a+A$. We obtain $a+A \leqq 2$ similarly, by choosing $x$ so that $\vartheta(x)=a x+o(x)$. Thus lemma 2 is proved.

Lemma 3. Let $x \rightarrow \infty$ so that $\vartheta(x)=A x+o(x)$. Then for any prime $p_{i} \leqq x$ except possible for a set of primes satisfying

$$
\begin{equation*}
\sum \frac{\log p}{p}=o(\log x) \tag{20}
\end{equation*}
$$

we have

$$
\begin{equation*}
\vartheta\left(\frac{x}{p_{i}}\right)=a \frac{x}{p_{i}}+o\left(\frac{x}{p_{i}}\right) \tag{21}
\end{equation*}
$$

Suppose the lemma is false. Then as in the proof of lemma 1 there exist two positive constants $b_{1}$ and $b_{2}$ so that for arbitrarily large $x$, satisfying $\vartheta(x)=A x+o(x)$, and for a set of primes satisfying $\sum \frac{\log p}{p}>b_{1} \log x$, we have

$$
\begin{equation*}
\vartheta\left(\frac{x}{p}\right)>\left(a+b_{2}\right) \frac{x}{p} \tag{22}
\end{equation*}
$$

But then we have from (22), lemma 2, (19) and II (as in the proof of lemma 1)

$$
\begin{array}{r}
a x \log x+o(x \log x)=\sum_{p \leqq x}(\log p) \vartheta\left(\frac{x}{p}\right)>b_{1}\left(a+b_{2}\right) x \log x+\left(1-b_{1}\right) a x \\
\log x+o(x \log x)=a x \log x+b_{1} b_{2} x \log x+o(x \log x)
\end{array}
$$

an evident contradiction. This proves lemma 3.
Lemma 4. Let $p_{1}$ be the smallest prime satisfying (21). Then $p_{1}<x^{\text {e }}$, and for all primes $p_{j}<x / p_{1}$ except possible for a set of primes satisfying

$$
\begin{equation*}
\sum \frac{\log p}{p}=o(\log x) \tag{23}
\end{equation*}
$$

we have

$$
\begin{equation*}
\vartheta\left(\frac{x}{p_{1} p_{j}}\right)=A \frac{x}{p_{1} p_{j}}+o\left(\frac{x}{p_{1} p_{j}}\right) \tag{24}
\end{equation*}
$$

$p_{1}<x^{e}$ follows immediately from (20) and II:` The second part of lemma 4 follows by applying the argument of lemma 3 to $x / p_{1}$ instead of $x$ and interchanging $A$ and $a$.

Now the deduction of the prime number theorem. Let $p_{i}$ be any prime satisfying (21). Assume $\frac{x}{p_{1} p_{j}}<\frac{x}{p_{i}}$. Then (since $\vartheta(x)$ is non-decreasing) from (21) and (24)

$$
a \frac{x}{p_{i}}+o\left(\frac{x}{p_{i}}\right) \leqq A \frac{x}{p_{1} p_{j}}+o\left(\frac{x}{p_{1} p_{j}}\right)
$$

or $p_{j}$ cannot lie in the interval

$$
I_{i}=\left[\frac{p_{i}}{p_{1}}, \frac{p_{i}}{p_{1}}\left(\frac{A}{a}-\delta\right)\right]
$$

where $\delta>0$ is an arbitrary fixed number. Hence all primes in $I_{i}$ must be "bad," i.e., they do not satisfy (24). But it immediately follows from (2) that

$$
\sum_{p \operatorname{in} I_{i}} \frac{\log p}{p}>\eta
$$

To obtain a contradiction to (23) it suffices to construct $c \log x$ disjoint intervals $I_{i}$. This can be accomplished in the same way as in the end of the proof of (2) (where the disjoint intervals $J_{i}{ }^{(r)}$ were constructed). This completes the first elementary proof of the prime number theorem.
4. Sketch of Selberg's simplification of the proof of (2).-If we can find two good primes satisfying

$$
\begin{equation*}
(1+c) p_{1}>p_{2}>(1+t) p_{1}, \quad c>\frac{C}{1+t} \tag{25}
\end{equation*}
$$

then (2) follows easily. The intervals $\left[\frac{x}{p_{1}}, \frac{x}{p_{1}}(1+c)\right],\left[\frac{x}{p_{2}}, \frac{x}{p_{2}}(1+c)\right]$, overlap. Thus (13), with $i=1$, holds. But then exactly as in lemma 1 there exists a prime $p$ so that

$$
\vartheta\left[\frac{x}{p_{1} p}(1+c)\right]-\vartheta\left(\frac{x}{p_{2} p}\right)=o\left(\frac{x}{p_{2} p}\right) .
$$

But this is impossible (by the definition of $C$ ) since

$$
\frac{x}{p_{1} p}(1+c) / \frac{x}{p_{2} p}=\frac{p_{2}(1+c)}{p_{1}}>1+C .
$$

Thus we only have to show that good primes satisfying (24) exist, and this can be accomplished by using III (a contradiction with $\sum_{p \text { good }} \frac{\log p}{p}=$ $[1+o(1)] \log x$ can be established similarly as in the previous proof).
5. The joint simplified proof of the prime number theorem.-

Lemma 5. Let $x_{2}>x_{1}$ and $x_{1} \rightarrow \infty$. Assume that $\vartheta\left(x_{1}\right)=A x_{1}+o\left(x_{1}\right)$ and $\vartheta\left(x_{2}\right)=a x_{2}+o\left(x_{2}\right)$, or $\vartheta\left(x_{1}\right)=a x_{1}+o\left(x_{1}\right)$ and $\vartheta\left(x_{2}\right)=A x_{2}+o\left(x_{2}\right)$. Then

$$
x_{2} / x_{1} \text { 文 } A / a+o(1) .
$$

Since $\vartheta(x)$ is non-decreasing we have in the first case

$$
a x_{2}+o\left(x_{2}\right) \geqslant A x_{1}+o\left(x_{1}\right) \text { or } x_{2} / x_{1} \gg A / a+o(1)
$$

In the second case we have by III $\vartheta\left(x_{2}\right)-\vartheta\left(x_{1}\right) \leqq 2\left(x_{2}-x_{1}\right)+o\left(x_{2}\right)$

$$
a x_{1}+2\left(x_{2}-x_{1}\right) \frac{2}{4} A x_{2}+o\left(x_{2}\right) \text { or }(2-A) x_{2} \geqslant(2-a) x_{1}+o\left(x_{2}\right) .
$$

Hence by lemma 2, $a x_{2} \geqslant A x_{1}+o\left(x_{2}\right)$. Thus again $x_{2} / x_{1} \geqslant A / a+o(1)$. q.e.d.

Put $1+D=\frac{A}{a}+\delta$ where $\delta$ is sufficiently small, and will be determined later. Next we prove the following result.
Lemma 6.

$$
\sum_{y \leqq p \leqq(1+D) y} \frac{\log p}{p}>\eta(\eta \text { independent of } y) .
$$

First we show that

$$
\begin{equation*}
\sum_{y \leqq p \leqq(1+D) y} \log p>\eta(1+D) y . \tag{26}
\end{equation*}
$$

If (26) is false then for a suitable sequence of $y$ 's we have $\vartheta[(1+D) y]-$ $v(y)=o(y)$. But then for these $y$ 's

$$
\frac{\vartheta[(1+D) y]}{(1+D) y}=\frac{\vartheta(y)+o(y)}{(1+D) y} \leqq \frac{A y+o(y)}{(1+D) y}<a-c_{1}
$$

which contradicts the definition of $a$. Thus (26) holds and lemma 6 follows immediately.

Choose now $x$ so that $\vartheta(x)=A x+o(x)$. Then by lemmas 3 and 4 we obtain ( $p_{1}, p_{i}$ and $p_{j}$ having the same meaning as in lemmas 3 and 4)

$$
\vartheta\left(\frac{x}{p_{1} p_{j}}\right)=A \frac{x}{p_{1} p_{j}}+o\left(\frac{x}{p_{1} p_{j}}\right), \quad \vartheta\left(\frac{x}{p_{i}}\right)=a \frac{x}{p_{i}}+o\left(\frac{x}{p_{i}}\right)
$$

From lemma 5 we obtain that for any fixed $\epsilon$ and sufficiently large $x$ (satisfying $\vartheta(x)=A x+o(x))$

$$
\text { either } \frac{x}{p_{i}}>\left(\frac{A}{a}-\epsilon\right) \frac{x}{p_{1} p_{j}} \text { or } \frac{x}{p_{i}}<\left(\frac{a}{A}+\epsilon\right) \frac{x}{p_{1} p_{j}}
$$

Hence $p$, cannot lie in the interval

$$
I_{i}=\left[\left(\frac{a}{A}+\varepsilon\right)_{p_{1}}^{p_{i}}\left(\frac{A}{a}-\epsilon\right) \frac{p_{i}}{p_{1}}\right] .
$$

Now if $\delta$ is small enough then $1+D \leqq\left(\frac{A}{a}-\epsilon\right) /\left(\frac{a}{A}+\epsilon\right)$. Hence by lemma 6

$$
\sum_{p \operatorname{in} I_{i}} \frac{\log p}{p}>\eta
$$

But by what has been said before all the primes in $I_{i}$ are bad (i.e., they do not satisfy (24)). Thus to arrive at a contradiction with (23) it will suffice as in the proof of (2) to construct $c \log x$ disjoint intervals $I_{i}$. This can be accomplished as in the proof of (2), which completes the proof of the prime number theorem.
6. Perhaps this last step can be carried out slightly more easily as follows: Put

$$
\begin{equation*}
S=\sum \frac{\log p_{i}}{p_{i}} \sum_{p_{\text {in }} I_{i}} \frac{\log p}{p} \tag{27}
\end{equation*}
$$

where $p_{i}$ runs through the primes satisfying (21). As stated before all the primes in $I_{i}$ are bad (i.e., they do not satisfy (24)). Thus we have from (27)

$$
\begin{equation*}
S>\eta \sum \frac{\log p_{i}}{p_{i}}>\frac{\eta}{2} \log x \tag{28}
\end{equation*}
$$

since by II and (20) $\Sigma \frac{\log p_{i}}{p_{i}}>1 / 2 \log x$ for large $x$.
On the other hand by interchanging the order of summation we obtain

$$
S=\sum \frac{\log p}{p} \sum_{p \text { in } J_{p}} \frac{\log p_{i}}{p_{i}}
$$

where $p$ runs through all the primes of all the intervals $I_{i}$ (each $p$ is, of course, counted only once) and $p_{i}$ runs through the primes satisfying (21) of the interval

$$
J_{p}=\left[p p_{1}\left(\frac{A}{a}-\epsilon\right)^{-1}, \quad p p_{1}\left(\frac{a}{A}+\epsilon\right)^{-1}\right] .
$$

We evidently have from $A<\infty$

$$
\sum_{p_{i} \text { in } J_{p}} \frac{\log p_{i}}{p_{i}}<c
$$

Hence

$$
\sum \frac{\log p}{p}>S / c
$$

or from (27)

$$
\sum \frac{\log p}{p}>\frac{\eta}{2 c} \log x
$$

which contradicts (22) and completes the proof.
${ }^{1}$ Selberg's proof of (1) is not yet published.
${ }^{2}$ See, for example, Landau, E., Handbuch der Lehre von der Verteilung der Primzahlen, § 19, or Ingham, A. E., The Distribution of Prime Numbers, p. 13.
${ }^{3}$ An analogous result is used in Selberg's proof of Dirichlet's theorem.
${ }^{4}$ See, for example, Landau, E., op. cit., §§18 and 26, or Ingham, A. E., op. cit., pp. 14,15 and 22.
