## Some theorems and remarks on interpolation.

By P. Erdõs in Syracuse, N. Y.

Throughout this paper $x_{1}^{(n)}, x_{2}^{(n)}, \ldots, x_{n}^{(n)}$ will denote the roots of the $n$-th Chebyshev polynomial $T_{n}(x)\left[T_{n}(\cos \vartheta)=\cos n \vartheta\right]$. $f(x)$ will denote a function continuous in $[-1,+1]$ and $L_{n}(f(x))$ will denote the Lagrange interpolation polynomial of $f(x)$ taken at the points $x_{i}^{(n)}(i=1,2, \ldots, n)$; in other words, $L_{n}(f(x))$ is a polynomial of degree not greater than $(n-1)$ for which ${ }^{1}$ )

$$
L_{n}\left(f\left(x_{i}^{(n)}\right)\right)=f\left(x_{i}^{(n)}\right) \quad(i=1,2, \ldots, n) .
$$

It is a well known result ${ }^{2}$ ) that for every $x_{0}$ there exists a continuous ${ }^{3}$ ) $f(x)$ so that $L_{n}\left(f\left(x_{0}\right)\right)$ does not converge to $f\left(x_{0}\right)$. In fact I proved ${ }^{4}$ ) that in marked contrast to a well known theorem of Fejér on Fourier series, if $x_{0}=\cos \frac{p}{q} \pi, p \equiv q \equiv 1(\bmod 2)$, there exists a continuous $f(x)$ so that $\lim \left|L_{n}\left(f\left(x_{0}\right)\right)\right|=\infty$, or there does not exist a sequence $n_{i}$ so that $L_{n_{i}}\left(f\left(x_{i j}\right)\right) \rightarrow f\left(x_{i 1}\right)$. Moreover ${ }^{4}$ ) for any $-\infty=c \leqq \infty$ and any such value of $x_{11}$ there exists a continuous $f(x)$ so that $L_{n}\left(f\left(x_{0}\right)\right) \rightarrow c$, i. e. $L_{n}\left(f\left(x_{0}\right)\right)$ can converge to any prescribed value. TURÁN and $\left.I^{5}\right)$ showed that if $x_{0} \neq \cos \frac{p}{q} \pi, p \equiv q \equiv 1(\bmod 2)$, then for every continuous $f(x)$ there exists a sequence $n_{i}$ so that $L_{n_{i}}\left(f\left(x_{0}\right)\right) \rightarrow f\left(x_{0}\right)$. Previously Marcinkiewicz ${ }^{6}$ ) has showed that, if the $x_{i}^{(n)}$ are the roots of $U_{n}(x)$,

[^0]then to a given continuous $f(x)$ and $-1 \leqq x_{0}^{\prime} \leqq 1$ there always exists a subsequence $n_{i}$, with $L_{n_{i}}\left(f\left(x_{0}^{\prime}\right)\right) \rightarrow f\left(x_{0}^{\prime}\right)$. It follows from resuits of TURÁN and myself ${ }^{5}$ ) that for a general class of point groups [which include the roots of both $T_{n}(x)$ and $U_{n}(x)$ ], to every continuous $f(x)$ there exists a sequence $n_{i}$ so that $L_{n_{i}}(f(x))$ converges to $f(x)$ almost everywhere.

Grunwald and Marcinkiewicz ${ }^{7}$ ) showed that there exists a continuous $f(x)$ so that $L_{n}(f(x))$ diverges for every $x$, in fact $\lim \sup L_{n}(f(x))=\infty$ for every $x$. The analogous question for Fourier series is as well known still unsolved and seems very difficult. Marcinkiewicz ${ }^{6}$ ) and Turán ${ }^{4}$ ) showed that for every $x_{0}$ there exists a continuous $f(x)$ so that

$$
\lim \sup \frac{1}{n} \sum_{k=1}^{n} L_{k}\left(f\left(x_{0}\right)\right)=\infty .
$$

In other words the arithmetic means of the Lagrange interpolation polynomials of a continuous function can diverge at a given point, again in marked contrast to the celebrated theorem of Fejer for Fourier series. Marcinkiewicz ${ }^{6}$ ) further showed that there exists a continuous $f(x)$ so that $\frac{1}{n} \sum_{k=1}^{n} L_{k}\left(f\left(x_{0}\right)\right)$ diverges in an arbitrarily given countable set, and he raised the problem whether there exists a continuous $f(x)$ so that $\frac{1}{n} \sum_{k=1}^{n} L_{k}\left(f\left(x_{0}\right)\right)$ should diverge almost everywhere. In a paper written 12 years ago $G$. Grunnwald and $I^{8}$ ) proved that there exists a continuous $f(x)$ so that $\frac{1}{n} \sum_{k=1}^{n} L_{k}(f(x))$ diverges for every $x$. While writing this paper I made the unfortunate discovery that our proof is erroneous. All that we prove is that there exists a continuous $f(x)$ so that for every $x$

$$
\begin{equation*}
\lim \sup \frac{1}{n} \sum_{k=1}^{n}\left|L_{k}(f(x))\right|=x \tag{1}
\end{equation*}
$$

In a view of the strong convergence of the arithmetic means of the Fourier series (1) seems not uninteresting, but of course it would be of interest to know whether (1) holds without the absolute value. I just succeeded to show that with a slight modification of our construction one can prove the existence of a continuous $f(x)$ so that for almost all $x$

[^1]\[

$$
\begin{equation*}
\limsup \frac{1}{n}\left(\sum_{k=1}^{n} L_{k}(f(x))\right)=\infty \tag{2}
\end{equation*}
$$

\]

The proof of (2) will be given at another occasion. At present I can not decide whether (2) can diverge for every $x$.

It is easy to prove that if for every $x,|f(x+h)-f(x)|=o\left(\left(\log \frac{1}{|h|}\right)^{-1}\right)$. $L_{n}(f(x))$ converges to $f(x)$. Marcinkiewicz ${ }^{6}$ ) proved that there exists an $f(x)$ satisfying for every $x$ the inequality $|f(x+h)-f(x)|=O\left(\left(\log \frac{1}{|h|}\right)^{-1}\right)$ such that $L_{n}(f(x))$ diverges almost everywhere. This result is interesting since it is easy to see that $\left|L_{n} f(x)\right|$ is uniformly bounded in this case. By using themethod of Grünwald ${ }^{7}$ ) it is easy to construct an $f(x)$ satisfying uniformly the "logarithmic" Lipschitz-condition $|f(x+h)-f(x)|=O\left(\left(\log \frac{1}{|h|}\right)^{-1}\right)$ and $L_{n}(f(x))$ diverges for every $x$. The proof follows the Grünwald-Marcinkiewicz ideas closely, thus wa do not give it.

In the present paper we prove the following
Theorem 1. For almost all $x$

$$
\frac{1}{n} \sum_{k=1}^{n}\left|L_{k}(f(x))\right|=o(\log \log n),
$$

if only $f(x)$ is continuous in $[-1,+1]$.
As an easy consequence of Theorem 1 we deduce
Theorem 2. Let $|f(x+h)-f(x)|=o\left(\left(\log \log \frac{1}{|h|}\right)^{-1}\right)$ uniformly in $[-1,+1]$. Then for almost all $x$

$$
\frac{1}{n} \sum_{k=1}^{n}\left(f(x)-L_{k}(f(x))\right)^{2} \rightarrow 0
$$

The interest of Theorem 1 and 2 is that they show that taking arithmetical means improves to some extent the convergence-properties of the Lagrangeinterpolatorical polynomials.

It can be shown that Theorems 1 and 2 are best possible in the following sense: Let $g(n) \rightarrow \infty$ arbitrarily slowly. Then there exists a continuous $f(x)$ so that for almost all $x$ there exists a sequence $n_{i}=n_{i}(x)$ so that

$$
\begin{equation*}
\frac{1}{n_{i}} \sum_{v=1}^{n_{i}}\left|L_{v}(f(x))\right|>\frac{\log \log n_{i}}{g\left(n_{i}\right)} . \tag{3}
\end{equation*}
$$

The same holds if we consider arithmetic means of higher order. (3) probably remains true without the absolute value, but this I can not prove.

Also there exists an $f(x)$ satisfying in $-\mathbf{1} \leqq x \leqq+1$ the condition
$|f(x+h)-f(x)|=O\left(\left(\log \log \frac{1}{|h|}\right)^{-1}\right)$ and so that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n}\left(f(x) L_{k}(f-(x))\right)^{2}=0 \tag{4}
\end{equation*}
$$

holds only in a set of measure 0 . This is not without interest since in (4) the $\lim$ sup is finite for almost $x$. [This can be shown by the same method as Theorem 2.] The proof of (3) and (4) is fairly complicated but is similar to the [correct part] of the argument of Grunwald and myself.

MARCINKIEWICZ ${ }^{6}$ ) proved that for every $g(n) \rightarrow \infty$ there exists a continuous $f(x)$ so that for almost all $x$ there exists a sequence $n_{i}=n_{i}(x)$, for which

$$
L_{n_{\mathrm{i}}}(f(x))>\frac{\log n_{i}}{g\left(n_{i}\right)} .
$$

By using the method of Grunwald ${ }^{7}$ ) it is easy to replace "almost all" by "all" in the result of MARCINKIEWICZ. Further for every $x_{0}$ there exists a continuous $f(x)$ so that

$$
\frac{1}{n_{i}} \sum_{k=1}^{n_{i}} L_{k}\left(f\left(x_{\mathrm{u}}\right)\right)>\frac{\log n_{i}}{g\left(n_{i}\right)} .
$$

We do not give the proofs of these two theorems since they do not contain any new idea.

Proof of Theorem 1. It will be sufficient to prove that if $f(x)$ is bounded and e. g. $|f(x)| \leqq \frac{1}{2}$ uniformly, then exists an absolute constant $c$ so that for almost all $x$ and $n>n_{0}=n_{0}(x)$

$$
\begin{equation*}
\left.\frac{1}{n} \sum_{k=1}^{n} \right\rvert\, L_{k}(f(x))<c \log \log n . \tag{5}
\end{equation*}
$$

Suppose (5) is proved. According to the theorem of Weierstrass we find a polynomial of degree $l, \varphi_{l}(x)$ so that $\left|f(x)-\varphi_{l}(x)\right|<\varepsilon$. By applying (5) to $\left(f(x)-\varphi_{i}(x)\right)$ and remarking that for $k>l L_{k}\left(\varphi_{l}(x)\right)=\varphi_{l}(x)$ we obtain

$$
\begin{gathered}
\frac{1}{n} \sum_{k=1}^{n}\left|L_{k}(f(x))\right|
\end{gathered}
$$

which proves Theorem 1. Thus we only have prove (5).
In the proof of (5) our principal tool will be the following result of Marcinkiewicz and Zygmund ${ }^{9}$ ): Let $|f(x)| \leqq 1$, then there exists an absolute constant $\lambda$ so that for every $a<\lambda$

$$
\begin{equation*}
\int_{-1}^{+1} \exp \left|a L_{k}(f(x))\right| d x<A=A(\lambda) \tag{6}
\end{equation*}
$$

[^2]where $A$ is independent of $k$. From (6) we obtain that there exists a constant $c_{1}$ so that
\[

$$
\begin{equation*}
M\left[x ;\left|L_{k}(f(x))\right|>c_{1} \log \log k\right]<\frac{1}{(\log k)^{10}} \tag{7}
\end{equation*}
$$

\]

( $M[x ; \ldots]$ denotes the measure of a set in $x$ satisfying a certain condition). Further it is well known that

$$
\begin{equation*}
\left|L_{k}(f(x))\right|<c_{2} \log k . \tag{8}
\end{equation*}
$$

Now we prove the following
Lemma. Let $g_{k}(x) \geq 0$ be defined in $[-1,+1]$. Assume that

$$
\begin{equation*}
M\left[x ; g_{k}(x)>c_{1} \log \log k\right]<\frac{1}{(\log k)^{10}} \tag{9}
\end{equation*}
$$

and
(10

$$
g_{k}(x)<c_{2} \log k \quad(k=2,3, \ldots, n) .
$$

Then if $c_{3}$ is sufficiently large, we have for almost all $x$ and sufficiently large $n>n_{0}(x)$

$$
G_{n}(x)=\frac{1}{n} \sum_{k=1}^{n} g_{k}(x)<c_{3} \log \log n
$$

The sequence $\left|L_{k}(f(x))\right|$ satisfies (9) and (10) [since it satisfies (7) and (8)]. Thus to prove Theorem 1 it will suffice to prove our lemma.

Proof of the Lemma. Define $S_{k}(x)$ as the set in $x$ for which $g_{k}(x)>c_{1} \log \log k$.

Let $\varphi_{k}(x)$ be 1 in $S_{k}(x)$ and 0 elsewhere. It follows from (10) that if $G_{n}(x)>c_{1} \log \log n$ then $x$ must be in $S_{k}(x)$ for at least $c_{4} n / \log n$ values of $k(1 \leqq k \leqq n)$. Thus by (9)

$$
\begin{align*}
& M\left[x ; G_{n}(x)>c_{1} \log \log n\right] \leqq M\left[x ; \sum_{k=1}^{n} \varphi_{k}(x)>\frac{c_{4} n}{\log n}\right]< \\
& <\frac{\log n}{c_{4} n} \int_{0}^{1}\left(\sum_{k=1}^{n} \varphi_{k}(x)\right) d x<\frac{\log n}{c_{4} n} \sum_{k=1}^{n} \frac{1}{(\log k)^{10}}<\frac{1}{(\log n)^{5}} . \tag{11}
\end{align*}
$$

Put $m_{r}=\left[e^{\sqrt{r}}\right]$. We obtain from (11) that

$$
\sum_{r=1}^{\infty} M\left[x ; G_{m_{r}}(x)>c_{1} \log \log m_{r}\right]<\sum_{r=1}^{\infty} \frac{1}{r^{2}}<\infty .
$$

Hence by a simple argument we obtain that for almost all $x$ and large enough $r>r_{0}(x)$

$$
\begin{equation*}
G_{m_{r}}(x)<c_{1} \log \log m_{r} . \tag{12}
\end{equation*}
$$

If $m_{r}<n<m_{r+1}$ we have by (10)
$m_{r}\left|G_{n}(x)\right|<n\left|G_{n}(x)\right|<m_{r}\left|G_{m_{r}}(x)\right|+c_{2}\left(m_{r+1}-m_{r}\right) \log n<m_{r}\left|G_{m_{r}}(x)\right|+\frac{c_{5} m_{r}}{\sqrt{r}} \log n$
i. e.

$$
\begin{equation*}
\left|G_{n}(x)\right|<\left|G_{m_{r}}(x)\right|+O(1) \tag{13}
\end{equation*}
$$

The Lemma now follows from (12) and (13). Thus Theorem 1 is proved.
Sketch of the proof of Theorem 2. It is well known that there exists a polynomial $\varphi_{l}(x)$ of degree $<\sqrt{n^{2}}$ so that

$$
\begin{equation*}
\left|f(x)-\varphi_{l}(x)\right|=o\left(\frac{1}{\log \log n}\right) \tag{14}
\end{equation*}
$$

We have

$$
\begin{gather*}
\frac{1}{n}\left[\sum_{k=1}^{n}\left(f(x)-L_{k}(f(x))\right)^{2}\right]=\frac{1}{n}\left[\sum_{k=1}^{n}\left(f(x)-L_{k}\left(f(x)-\varphi_{l}(x)\right)-L_{k}\left(f_{l}(x)\right)\right)^{2}\right] \leqq \\
\vdots \frac{1}{n} \sum_{k=1}^{n}\left(f(x)-L_{k}\left(\varphi_{l}(x)\right)\right)^{2}+\frac{2}{n}\left[\sum_{k=1}^{n}\left(f(x)-L_{k}\left(\varphi_{l}(x)\right)\right) \cdot\left(L_{k}\left(f(x)-\varphi_{l}(x)\right)\right)\right]+  \tag{15}\\
+\frac{1}{n} \sum_{k=1}^{n} L_{k}\left(f(x)-\varphi_{l}(x)\right)^{2}=\Sigma_{1}+\Sigma_{2}+\Sigma_{3} .
\end{gather*}
$$

From (14) and (8) we obtain $\Sigma_{1}=o(1)$ since $L_{k}\left(\varphi_{l}(x)\right)=\varphi_{l}(x)$ for $k>\sqrt{n}$. From (14) and (8) we have

$$
\begin{aligned}
\Sigma_{2} & <\frac{\varepsilon}{n \log \log n} \sum_{k=1}^{n}\left|L_{k}\left(f(x)-\varphi_{l}(x)\right)\right|+o(1)< \\
& <\frac{\varepsilon}{n \log \log n}\left(\sum_{k=1}^{n}\left|L_{k}(f(x))\right|+\sum_{k=1}^{n}\left|L_{k}\left(\varphi_{l}(x)\right)\right|\right)+o(1)< \\
& <\frac{2 \varepsilon}{n \log \log n} \sum_{k=1}^{n}\left|L_{k}(f(x))\right|+o(1)=o(1)
\end{aligned}
$$

for almost all $x$ by Theorem 1. Now we investigate $\Sigma_{3}$. Put $s_{r}=e^{r^{1 / 4}}$. It suffices, to show that for almost all $x$

$$
\begin{equation*}
\Sigma_{3}^{\prime}=\frac{1}{s_{r}} \sum_{1 \leqq k \leqq s_{r}} L_{k}\left(f(x)-\varphi_{l}(x)\right)^{2}=o(1) \tag{16}
\end{equation*}
$$

For if (16) is proved, put $s_{r}<n<s_{r+1}$. Clearly

$$
\begin{gathered}
\Sigma_{3} \leqq \Sigma_{3}^{\prime}+\frac{2}{n}\left[\sum_{k=s_{r}}^{s_{r+1}} L_{k}\left(f(x)-\varphi_{l}^{\prime}(x)\right)^{2}\right]<\Sigma_{3}^{\prime}+\frac{2\left(s_{r+1}-s_{r}\right)}{n}\left(c_{2} \log n\right)^{2}<\Sigma_{3}^{\prime}+o(1) \\
\left(\text { since }\left(s_{r+1}-s_{r}\right)<c \frac{s_{r}}{r^{3_{4} / 4}}<c \frac{s_{r}}{(\log n)^{3}}\right),
\end{gathered}
$$

or for almost all $x \Sigma_{3}=o(1)$. Thus we have only to prove (16).
The proof of (16) is similar to that of our lemma. Denote by $S_{k}^{\prime}(x)$ the set in $x$ for which $L_{k}\left(f(x)-\varphi_{l}(x)\right)^{2}>\varepsilon$. By (14) and the theorem of MARCINKIEWICZ-ZyGMUND ${ }^{9}$ ) the measure of $S_{k}^{\prime}(x)$ is less than $\frac{1}{(\log k)^{10}}$. Thus from (8) if $\Sigma_{3}^{\left(s_{r}\right)}>\varepsilon s_{r}, x$ has to lie in at least $\frac{c_{5} S_{r}}{\left(\log s_{r}\right)^{2}}$ sets $S_{k}^{\prime}(x), 1 \leqq k \leqq s_{r}$.

But then, as in the proof of the lemma,

$$
M\left[x ; \Sigma_{3}^{\prime}>\varepsilon s_{r}\right]<\frac{c_{6}\left(\log s_{r}\right)^{2}}{s_{r}} \sum_{k \leq s_{r}} \frac{1}{(\log k)^{10}}<\frac{r_{7}}{\left(\log s_{r}\right)^{8}}
$$

or

$$
\sum_{r=1}^{\infty} M\left[x ; \Sigma_{3}^{\prime}>\varepsilon S_{r}\right]<\sum_{r=1}^{\infty} \frac{c_{7}}{r^{2}}<\infty
$$

which proves (16) and completes the proof of Theorem 2.
(Received July 9, 1949.)

[^0]:    ${ }^{1}$ ) There will be no misunderstanding writing $L_{n}\left(f\left(x_{i}^{(n)}\right)\right)$ instead of $L_{n}(f(x))_{x=r_{i}^{(n)}}^{(n)}$ throughout this paper.
