## Some problems and results in elementary number theory.

By P. Erdõs in Aberdeen (Scotland).

Throughout this paper $c_{1}, c_{2}, \ldots$ denote absolute constants, $p_{1}, p_{2}, \ldots$ are primes, $P_{1}, P_{2}, \ldots$ is the sequence of all primes, letters $u, x, y, n, a, b$, etc. denote positive integers.

Denote by $u_{1}=1<u_{2}<\ldots$ the sequence of integers of the form $x^{2}+y^{2}$. Chowla and Bambah remarked that $u_{i-1}-u_{i}<c_{1} u_{i}^{\prime+}$. It has been conjectured that $u_{i+1}-u_{i}=o\left(u_{i}^{*}\right)$. In other words for any $\varepsilon>0$ an sufficiently large $n$ there always is an integer of the form $x^{2}+y^{2}$ in the interval ( $n, n+\varepsilon n^{2}$ ). This conjencture is still unproved. This is rather surprising since the proof of Bambah and Chowla is immediate. It suffices to put $u_{i}=x^{2}+y^{2}$ where

$$
x^{2}<u_{i+1} \leqq(x+1)^{2}, y^{2}<u_{i+1}-x^{2} \leqq(y+1)^{2} .
$$

Turán (in a letter) observed that it is easy to prove that

$$
\begin{equation*}
u_{i+1}-u_{i}>c_{2} \frac{\log u_{i}}{\log \log u_{i}} \tag{1}
\end{equation*}
$$

for inifinitely many $i$. He asked whether I can improve (1).
In fact I can show that for infinitely many $i$

$$
\begin{equation*}
u_{i+1}-u_{i}>c_{2} \frac{\log u_{i}}{\left(\log \log u_{i}\right)^{\sigma_{2}}} . \tag{2}
\end{equation*}
$$

In fact I prove a somewhat more general theorem. Let $p_{1}<p_{2}<\ldots$ be a sequence of primes satisfying

$$
\sum_{p_{i}<x} \frac{1}{p_{i}}=f(x) \rightarrow \infty \quad \text { as } x \rightarrow \infty,
$$

in other words $\sum \frac{1}{p_{i}}=\infty$. Denote by $v_{1}<r_{2}<\ldots$ the integers which either are not divisible by $p_{i}$ or are divisible by $p_{i}^{2}$. Then we prove

Theorem 1. For infinitely many $i$ we have

$$
\begin{equation*}
r_{i-1}-v_{i}>c_{i} e^{f\left(\log e_{i}\right)} \frac{\log v_{i}}{\log \log v_{i}} . \tag{3}
\end{equation*}
$$

Before proving Theorem 1 we show that Theorem 1 implies (2). If the $p$; are the primes $\equiv 3(\bmod 4)$, then as is well known the $u$ 's are included among the $r$ 's, also it is well known that

$$
\underset{\substack{p=3\left(\bmod _{4} 4\right) \\ p \leqq x}}{ } \frac{1}{p}=\frac{1}{2} \log \log x+O(1) .
$$

Thus from $e^{z}>1+z$,

$$
e^{f\left(\log c_{j}\right)}>c_{5}\left(\log \log c_{i}\right)^{\prime}+,
$$

or (3) implies (2).
It seems rather difficult to prove a stronger result than Theorem 1. In fact if $w_{1}, w_{2}, \ldots$ denote the integers not divisible by any $p_{i}$, the $w$ 's are clearly included among the $v$ 's; but nevertheless 1 cannot prove any stronger result than (3) for the w's.

Before proving Theorem 1 we state a few well known results on primes which we will need. Let denote by $D_{i}(y)$ the number of integers less than $y$ which are not divisible by $p_{1}, p_{2}, \ldots, p_{i}$. It is well known [and follows from Brun's method ${ }^{1}$ )] that there exist two absolute constants $c_{6}$ and $c_{7}$ so that

$$
\begin{equation*}
D_{l}(y)<c_{6 i} y \prod_{y_{i}<y^{c_{z}}}\left(1-\frac{1}{p_{i}}\right) . \tag{4}
\end{equation*}
$$

Now [with $\exp z=e^{3}$ ]
since

$$
\begin{equation*}
\left.\sum \frac{1}{P}=\log \log x+O, 1\right) \tag{6}
\end{equation*}
$$

Thus from (4) and (5)

$$
\begin{equation*}
D_{i}(y)<c_{9} y \prod_{y i}\left(1-\frac{1}{p_{i}}\right) \quad\left(c_{9}=\frac{c_{5}}{c_{N}}\right) . \tag{7}
\end{equation*}
$$

Now we prove Theorem 1. Since $\sum \frac{1}{p_{i}}=\infty$, there exist infinitely many $k$ satisfying $p_{k}<k^{2}$. Put

$$
l=\left[\frac{k}{2}\right], t=c_{10} k e^{f\left(\mu_{k}\right),}
$$

where $c_{10}$ is sufficiently small and will be determined later. Denote by $a_{1}, a_{2}, \ldots, a_{t}$ the integers not excending $t$ which are either not divisible by $p_{i},(1 \leqq i \leqq l)$ or are divisible by $p_{i}^{2}$. First we prove that for sufficiently large $k$

$$
\begin{equation*}
z<l \tag{8}
\end{equation*}
$$

${ }^{1}$ ) See for example P. Erdős, On the easier Waring problem for powers of primes. I. Proc. Cambridge Phil. Soc. 33 (1937), 6-12.

First we show that for sufficiently large $k$

$$
\begin{equation*}
k<t<k(\log k)^{2} . \tag{9}
\end{equation*}
$$

Obviously $t>k$ since $f\left(p_{k}\right) \rightarrow \infty, t<k(\log k)^{2}$ follows immediately from (6). To prove (8) write $a_{j}=b_{j} d_{j}$ where $d_{j}$ is not divisible by any of $p_{1}, p_{2}, \ldots, p_{i}$ and $b_{j}$ is entirely composed of the $p_{i}, 1 \leqq i \leqq l$ and all the exponents of its prime factors are greater than 1 . We split the $a$ 's into two classes. In the first class are the $a^{\prime}$ 's with $b_{i} \geqq t^{\prime \prime 2}$ and in the second class the $a$ 's with $b_{j}<t^{\prime}$. Clearly $b_{j}$ is divisible by a square not less than $b_{j}^{1 a^{3}}\left(b_{j}=p_{1}^{2 \alpha_{1}} \ldots p_{k}^{2 \beta_{1}-1} \ldots\right)$ and the largest square dividing $b_{j}$ is $p_{1}^{2 \alpha_{1}} \ldots p_{i}^{2 \beta_{1}} \ldots$ which is clearly $\geqq b_{i}^{2 /}$. Thus the integers of the first class are divisible by a square $\geqq t^{1 / 3}$. Therefore by (9) the number of the $a$ 's of the first class is not greater than

$$
\begin{equation*}
\sum_{m=t^{1 / 2}} \frac{t}{m^{2}}<t=k(\log k)^{2}<\frac{k}{4} . \tag{10}
\end{equation*}
$$

The number of integers of the second class clearly equals

$$
\begin{equation*}
\sum_{v_{j} \leq T_{i}^{\prime}} D_{l}\left(\frac{t}{b_{j}}\right) . \tag{11}
\end{equation*}
$$

We have by (9) and $p_{i}<p_{k}<k^{2}$

$$
\left(\frac{t}{b_{j}}\right)^{4} \geqq t^{2}>p_{k} .
$$

Thus by (7)

$$
D_{i}\left(\frac{t}{b_{j}}\right)<c_{9} \frac{t}{b_{j}} \prod_{k=1}^{k}\left(1-\frac{1}{p_{i}}\right)
$$

Thus

$$
\begin{equation*}
D_{i}\left(\frac{t}{b_{j}}\right)<c_{9} \frac{t}{b_{j}} \prod_{i=1}^{k}\left(1-\frac{1}{p_{i}}\right)<c_{11} \frac{t}{b_{j}} e^{-f\left(p_{i}\right)}=c_{10} c_{11} \frac{k}{b_{j}} . \tag{12}
\end{equation*}
$$

Now

$$
\begin{equation*}
\sum \frac{1}{b_{j}}<\sum_{j=1}^{\infty} \frac{1}{r^{2}} \sum_{k=1}^{\infty} \frac{1}{s^{3}}<c_{12} \tag{13}
\end{equation*}
$$

Thus from (10), (12) and (13) the number of integers of the second class. is less than

$$
\begin{equation*}
c_{10} c_{11} c_{12} k<\frac{k}{4} \tag{14}
\end{equation*}
$$

for sufficiently small $c_{10}$. Thus (10) and (14) imply (8).
Let now $0<x<\left(p_{1} p_{2} \ldots p_{l i}\right)^{2}$ satisfy the following congruences :

$$
\begin{gathered}
x \equiv 0\left(\bmod \left(p_{1} p_{2} \cdots p_{i}\right)^{2}\right) \\
x+a_{i} \equiv p_{l+i}\left(\bmod p_{l+i}^{2}\right), \quad i=1,2, \cdots, z
\end{gathered}
$$

Since by (8) $z<l$, all the $p$ 's are less than $p_{i j}$.

Now we show that none of the integers

$$
x+u, 0<u \leqq t
$$

are $r$ 's. If $u$ is not one of the $a$ 's then there exists a $p_{i}, 1 \leqq i \leqq l$ so that $p_{i} \mid u, p_{i}^{2} \nsucc u$. But then clearly $p_{i} \mid(x+u)$, $p_{i}^{2} \nsucc(x+u)$, i. e, $x+u$ is not a $c$. If $u=a_{i}$ then $p_{i+i} \mid(x+u), p_{i+i}^{2} X(x+u)$ i. e. $x+u$ is not a $c$. Define now

$$
\iota_{j} \leqq x<x-t<r_{j-1} .
$$

Thus

$$
\begin{equation*}
r_{j+1}-v_{j}>t=c_{10} k e^{f\left(p_{k}\right)} . \tag{15}
\end{equation*}
$$

Further from $p_{k i}<k^{2}$

$$
r_{j} \leqq x<\left(p_{1} p_{2} \cdots p_{k}\right)^{2}<p_{k}^{2 k}<k^{1 k},
$$

hence

$$
\begin{equation*}
k>c_{13} \frac{\log r_{j}}{\log \log r_{j}} . \tag{16}
\end{equation*}
$$

Thus from (15) and (16)

$$
\begin{equation*}
r_{j+1}-r_{j}>c_{14} e^{f\left(r_{k}\right)} \cdot \frac{\log r_{j}}{\log \log r_{j}} . \tag{17}
\end{equation*}
$$

From (16) $k^{2}>\log v_{j}$. Thus from (6)

$$
\begin{equation*}
f\left(\log r_{j}\right)-f\left(p_{k}\right) \leqq f\left(k^{2}\right)-f\left(p_{k i}\right) \leqq f\left(k^{2}\right)-f(k)<c_{15} . \tag{18}
\end{equation*}
$$

Hence finally from (17) and (18)

$$
v_{j-1}-r_{j}>c_{4} e^{f\left(\log v_{j}\right)} \frac{\log r_{j}}{\log \log r_{j}}
$$

which proves Theorem 1.
It is not difficult to show that Theorem 1 remains true if we do not assume that the $p$ 's are primes but only assume that $\left(p_{i}, p_{j}\right)=1$.

As stated before it seems hard to improve Theorem 1. In only succeeded in doing this if we assume that

$$
\begin{equation*}
\sum \frac{1}{q}<\infty \tag{19}
\end{equation*}
$$

where $q$ runs through the primes which are not $p$ 's. In this case Theorem 1 gives

$$
r_{i+1}-r_{i}>c_{16} \log r_{i},
$$

and I can prove $\lim \frac{r_{i+1}-r_{i}}{\log r_{i}}=\infty$.
If we only want to prove (2) we do not need Brun's method. We can use instead LaNDAU's well known result that the number of integers $\leqq t$ of the form $u^{2}+r^{2}$ is $O\left(\frac{t}{(\log t)^{2}}\right)$. In fact LaNDAU showed that it is

$$
A \frac{t}{(\log t)^{1}=}+o \frac{t}{(\log t)^{t}} .
$$

Let us now assume that $\sum \frac{1}{p_{i}}<\infty$. Perhaps the most interesting case is if the $r$ 's are the squarefree numbers. Here the $p$ 's are not primes but the squares of primes. Denote by $s_{1}<s_{2}<\cdots$ the sequence of squarefree numbres. Our above method gives that for infinitely many $i$

$$
\begin{equation*}
s_{i+1}-s_{i}>(1+o(1)) \frac{\pi^{3}}{6} \frac{\log s_{i}}{\log \log s_{i}} . \tag{20}
\end{equation*}
$$

I do not know if (20) has been published before, but it was certainly known to several mathematicians e. g. Bateman, Chowla and Mirsky. The curious thing is that it seems to be extremely hard to replace $\frac{\pi^{2}}{6}$ by any larger constant, in fact it seems possible that for $i>i_{0}$

$$
\begin{equation*}
s_{i+1}-s_{i}<(1+\varepsilon) \frac{\pi^{2}}{6} \frac{\log s_{i}}{\log \log s_{i}} . \tag{21}
\end{equation*}
$$

The strongest result in the direction of (21) is due to Roth ${ }^{2}$ ) and states that

$$
\begin{equation*}
s_{i+1}-s_{i}<s_{i}^{3_{i}}\left(\log s_{i}\right)^{\frac{4}{15}+z} . \tag{22}
\end{equation*}
$$

When I heard of Roth's result I thought of trying to prove that for every $a$

$$
\begin{equation*}
\sum_{x_{i}+1}\left(s_{i+1}-s_{k}\right)^{\alpha}=C_{k} x+o(x) \tag{23}
\end{equation*}
$$

The proof of (23) seems very difficult; it would of course imply $s_{i+1}-s_{i}=o\left(s_{i}^{i}\right)$. In can prove (23) only if $\alpha<A$ where $A$ is a certain constant between 2 ane 3. Here I only sketch the proof for $\alpha=2$.

Denote by $g_{t}(x)$ the number of $s_{i}<x$ satisfying $s_{i+1}-s_{i}=t$.
Lemma 1. For fixed $t$ as $x \rightarrow \infty$

$$
g_{t}(x)=\beta_{t} x+o(x) .
$$

In other words the density of the $s_{i}$ with $s_{i+1}-\mathrm{s}_{i}=t$ exists.
Lemma 1 is known. ${ }^{3}$ )
Lemma 2. There exists an absolute constant $c_{17}$ so that

$$
\sum_{i=1} g_{l}(x)<c_{17} \frac{x}{t^{2}(\log t)^{2}}
$$

Put $s_{i+1}-s_{i}=r>t$. We show that there are at least $\frac{r}{16}$ integers $z$ satisfying $s_{i}<z<s_{i+1}$ which are divisible by the square of a prime $P>\frac{t \log t}{100}$. To
${ }^{2}$ ) K. F. Rотн, On the gaps between squarefree numbers, Journal London Math. Soc. Vol. 26 (1951), 263-268.
${ }^{3}$ ) L. Mirsky, Arithmetical pattern problems relating to divisibility by $r$-th powers. Proc. London Math. Soc. 50 (1949), 497-508. - See Theorem 4, p. 507.
show this we observe that the number of integers $s_{i}<y<s_{i+1}$ which are divisible by the square $P^{2}$ of a prime $P \leqq \frac{t \log t}{100}$ is at most

$$
\begin{equation*}
\sum_{P \leqq \frac{t \log t}{100}}\left(\left[\frac{r}{P^{2}}\right]+1\right)<r \sum \frac{1}{P^{2}}+\pi\left(\frac{t \log t}{100}\right)<\frac{3}{4} r+\frac{r}{8}=\frac{7}{8} r \tag{24}
\end{equation*}
$$

since $\sum \frac{1}{p^{2}}<\frac{1}{4}+\frac{1}{2.3}+\frac{1}{3.4}+\cdots<\frac{3}{4}$ and by the results of TCHEBICHEFF for $t>1$

$$
\pi\left(\frac{t \log t}{100}\right)<\frac{t}{8}<\frac{r}{8}
$$

Since by assumption all the $r-1$ integers $z$ satisfying $s_{i}<z<s_{i+1}$ are divisable by squares, we obtain from (24) that for $r>16$ there are at least $r-1-\frac{7}{8} r>\frac{r}{16}$ integers $z$ divisible by a $P^{2}$ with $P>\frac{t \log t}{100}$. [For $r \leqq 16$, $t<16, \frac{t \log t}{100}<1$ thus all the $r-1$ integers are divisible by $P^{2}$ with $P>\frac{t \log t}{100}$.] Hence our assertion is proved. Thus there are at least

$$
\begin{equation*}
\frac{1}{16_{\substack{s_{i+1}}}^{s_{i+1}-s_{i}>t}} \sum_{\substack{x\\}}\left(s_{i+1}-s_{i}\right) \tag{25}
\end{equation*}
$$

integers not exceeding $x$ which are divisible by the square of a prime $P>\frac{t \log t}{100}$. But the number of these integers is less than

$$
\begin{equation*}
\sum_{P>\frac{t \log t}{1001}} \frac{x}{P^{2}}<c_{18} \frac{x}{t(\log t)^{2}} \tag{26}
\end{equation*}
$$

[since $\left.P_{k}>c_{11} k \log k\right]$. Thus from (25) and (26)

$$
\begin{equation*}
\sum_{\substack{s_{i+1} \leqq x \\ s_{i+1}-s_{i}>t}}\left(s_{i+1}-s_{i}\right)<16 c_{18} \frac{x}{t(\log t)^{2}} \tag{27}
\end{equation*}
$$

or the number of $i$ 's with $s_{i+1} \leqq x, s_{i+1}-s_{i}>t$ is less than
which proves Lemma 2.

$$
16 c_{18} \frac{x}{t^{2}(\log t)^{2}}
$$

From Lemma 2 we have by a simple computation that for every $\varepsilon>0$ there exist an $r$ so that

$$
\begin{align*}
\sum_{\substack{s_{i}+1 \leq, r \\
x_{i}+1-s_{i}}}\left(s^{i}+1-s_{i}\right)^{2} & =\sum_{\substack{j=1}}^{x} \sum_{\substack{x_{i+1} \leq, r \\
2^{r+j}<s_{i}+1-s_{j} \leq 2^{++j+1}}}\left(s_{i+1}-s_{i}\right)^{2}<\sum_{j=1}^{\infty} 2^{2 r+2 j+2} \sum_{l<2^{r+j}} g_{l}(x)<  \tag{28}\\
& <c_{17} x \sum_{j=1}^{\infty} \frac{2^{2,-2}+j^{2}+2}{2^{2,+2 j}(r+j)^{2}}<\varepsilon x .
\end{align*}
$$

## Further from Lemma 1

$$
\begin{equation*}
\sum_{\substack{x_{i+1} \leq x \\ x_{i+1}-s_{i} \leqq 2^{r}}}\left(s_{i-1}-s_{i}\right)^{2}=x \sum_{i=1}^{2^{\prime}} t^{2} \beta_{i}+o(x) \tag{29}
\end{equation*}
$$

From (28) and (29) we obtain by a simple argument that

$$
\sum_{i_{i+1} \leq i=i}\left(s_{i+1}-s_{i}\right)^{2}=O(x), \sum_{i=1}^{\infty} t^{2} \beta_{i}<\infty
$$

and finally that

$$
\sum_{x_{i+1} \leq}\left(s_{i-1}-s_{i}\right)^{2}=x \sum_{t=1}^{\infty} t^{2} \hat{\beta}_{t}+o(x)
$$

which proves (23) for $\varepsilon=2$.
Lemma 1 can be generalized as follows: Let $a_{1}<a_{2}<\cdots$ be any sequence of integers. Denote by $b_{1}<b_{2}<\cdots$ the set of integers not divisible by any of the $a$ 's. Assume that the density of the $b$ 's exists. [This is certainly the case if $\geq \frac{1}{a_{i}}<\infty$.] Then the density of integers satisfying $b_{i-1}-b_{i}=t$ also exists. We do not discuss the proof, but only remark that it follows almost immediately from the following theorem of DAVENPORT and myself ${ }^{4}$ ): Denote by $c_{i k}$ the density of the integers not divisible by $a_{i}, a_{2}, \ldots, a_{k}$, and by $c$ the density of the integers not divisible by $a_{1}, a_{2}, \ldots$. Then $c=\lim _{k \rightarrow \infty} c_{k}$.

By the theorem of DAVENPORT and myself it is easy to see that if the density of the $b$ 's exists and is positive, then to every $\varepsilon$ there exist a $c_{\mathrm{s}}$ so that

$$
\sum_{\substack{b_{i+1}+1 \\ b_{i}+b_{j}}}\left(b_{i-1}-b_{i}\right)<\varepsilon x .
$$

On the other hand no stronger result can hold in general even if - $\frac{1}{a_{i}}<\infty$. Define the $a$ 's for example as the integers in the intervals

$$
\begin{aligned}
\left|2^{k}, 2^{2}\left(1+\frac{1}{k^{2}}\right)\right|, \text { then }-\frac{1}{a_{j}} \sim \text { but } \\
\qquad \lim _{x \rightarrow 2} \frac{1}{x} \geq\left(b_{i-1}-b_{i}\right)^{\prime}=\sim
\end{aligned}
$$

I do not know whether this can happen if $\geq \frac{1}{a_{i}}<\sim$ and $\left(a_{i}, a_{i}\right)=1$.
(Recieved May 4, 1951.)
