# SOME REMARKS ON SET THEORY, IX. COMBINATORIAL PROBLEMS IN MEASURE THEORY AND SET THEORY 

P. Erdös and A. Hajnal<br>To the memory of our friend and collaborator, J. Czipszer

## 1. INTRODUCTION

A well-known theorem of Ramsay [12; p. 264] states that if the k-tuples of an infinite set S are split into a finite number of classes, then there exists an infinite subset of S all of whose k -tuples belong to the same class. (For $\mathrm{k}=1$, this is trivial.)

Suppose that with each element $x$ of an infinite set $S$ there is associated a measurable set $\mathrm{F}(\mathrm{x})$ in the interval $[0,1]$. It is known that if the measure $\mathrm{m}(\mathrm{F}(\mathrm{x}))$ of the sets $F(x)$ are bounded away from zero, then some real number $c$ is contained in infinitely many sets $\mathrm{F}(\mathrm{x})$. For the sake of completeness, we prove this.

It clearly suffices to consider the case where $S$ is the set of natural numbers. For each $t$ in S, let

$$
G_{t}=\bigcup_{n=t}^{\infty} F(n) \quad \text { and } \quad G=\bigcap_{t=1}^{\infty} G_{t} \text {, }
$$

where $m(F(n)) \geq u>0$ for $n \in S$. Clearly, $m\left(G_{t}\right) \geq u$ and $G_{t+1} \subset G_{t}(t=1,2, \cdots)$ (throughout the paper, the symbol $\subset$ refers to inclusion in the broad sense). Thus, by a classical theorem of Lebesgue, $m(G) \geq u$. Since each $c$ in $G$ is contained in infinitely many sets $F(t)$, this completes the proof.

Now, in analogy to Ramsay's theorem, one might consider the following problem. Suppose that, for some $u>0$, there is associated with each k-tuple $X=\left\{x_{1}, \cdots, x_{k}\right\}$ of elements of an infinite set $S$ a measurable set $F(X)$ of $[0,1]$ such that $m(F(X)) \geq u$. Does there always exist an infinite subset $S^{\prime}$ of $S$ such that the sets $F(X)$ corresponding to the k-tuples $X$ of $S^{\prime}$ have a nonempty intersection? We study this and related questions. In the course of our investigation we are led to a surprising number of unsolved problems.

All of our results concern the case $k=2$, but we shall state some problems for $\mathrm{k}>2$ as well.

Instead of choosing a measurable subset of $[0,1]$ for every $k$-tuple of a set $S$, we could choose an abstract set having certain properties. Interesting problems of a new type then arise, which we discuss briefly in Section 4. There we investigate some purely graph-theoretical questions, and in particular we give a simple construction of graphs that contain no triangle and have arbitrarily high chromatic numbers.

## 2. NOTATION AND DEFINITIONS

We adopt the following notation:

```
cardinal numbers: a, b, m, n;
ordinal numbers: }\alpha,\beta,\cdots,\nu,\mu,\cdots
nonnegative integers: i, j, k, l, r, s, t;
real numbers in [0, 1]:c, u,v, u},\mp@subsup{u}{1}{},\mp@subsup{u}{2}{},\cdots,0\mathrm{ ;
abstract sets: S, X, Y;
```

```
elements of sets: x, y, \cdots;
the least cardinal number greater than n: n+.
```

The symbols $[\mathrm{S}]^{\mathrm{a}}$ and $[\mathrm{S}]^{<a}$ denote the classes of subsets of S that have cardinality a and less than a, respectively. If X and Y are disjoint sets, we write

$$
[\mathrm{X}, \mathrm{Y}]=\{(\mathrm{x}, \mathrm{y}) \mid \mathrm{x} \in \mathrm{X} \text { and } \mathrm{y} \in \mathrm{Y}\} .
$$

Let S be a set of power m , and let F denote a function that associates a measurable subset of $[0,1]$ with each $X \in[S]^{k}$. For brevity, we shall say that $F$ is a setfunction on $S$ of type k. (The symbol $F$ will always denote a set-function.) Suppose $0 \leq \mathrm{u} \leq 1$. If, for each $\mathrm{x} \in[\mathrm{S}]^{\mathrm{k}}, \mathrm{m}(\mathrm{F}(\mathrm{X})) \geq \mathrm{u}$ or $\mathrm{m}(\mathrm{F}(\mathrm{X}))>\mathrm{u}$, we say that F is of order at least $u$ or of order greater than $u$, respectively.

Let Z be a subset of $[\mathrm{S}]^{\mathrm{k}}$. If

$$
\bigcap_{X \in Z} F(X) \neq \emptyset
$$

we say that Z possesses property $\mathscr{P}$ (with respect to F ).
With specific reference to the problems mentioned in Section 1, we introduce the following symbols.

$$
\begin{equation*}
(m, k, u) \Rightarrow n \quad \text { and } \quad(m, k,>u) \Rightarrow n \tag{1}
\end{equation*}
$$

represent the respective statements: If $\overline{\bar{S}}=m$ and if $F$ is a set-function on $S$ of type $k$ and of order at least $u$ (of order greater than $u$ ), then $S$ has a subset $S^{\prime}$, of cardinality $n$, such that $\left[\mathrm{S}^{\prime}\right]^{\mathrm{k}}$ possesses property $\mathscr{P}$. To say that a statement involving the symbol $\Rightarrow$ is false, we replace $\Rightarrow$ by $\nRightarrow$.

The symbolic statement

$$
\begin{equation*}
(\mathrm{m}, \mathrm{u}) \Rightarrow\left(\mathrm{n}_{1}, \mathrm{n}_{2}\right) \tag{2}
\end{equation*}
$$

means that if $\overline{\bar{S}}=m$ and $F$ is a set-function on $S$, of type 2 and of order at least $u$, then there exist disjoint subsets $S_{1}$ and $S_{2}$ of $S$ with cardinality $n_{1}$ and $n_{2}$, respectively, such that $\left[S_{1}, S_{2}\right]$ possesses property $\mathscr{P}$. Instead of (m, $\left.2, u\right) \Rightarrow n$, we often write that S contains a complete graph of power n that has property $\mathscr{P}$ (with respect to F ).

The theorems in whose proofs we use the generalized continuum hypothesis are marked by an asterisk: (*).

$$
\text { 3. THE CASE } \mathrm{m} \leq \boldsymbol{\aleph}_{0}
$$

THEOREM 1. Suppose that $2 \leq \mathrm{r}<\omega$. Then $\left(\boldsymbol{\aleph}_{0}, 2, \mathrm{u}\right) \Rightarrow \mathrm{r}+1$ if and only if $u>1-1 / r$.

Proof. First we show the condition that $\mathrm{u}>1-1 / \mathrm{r}$ to be necessary. If $\theta \in(0,1)$, let

$$
\begin{equation*}
\theta=\sum_{\mathrm{t}=1}^{\infty} \frac{\mathrm{s}_{\mathrm{t}}}{\mathrm{r}^{\mathrm{t}}} \quad\left(0 \leq \mathrm{s}_{\mathrm{t}}<\mathrm{r}\right) \tag{3}
\end{equation*}
$$

be its $r$-ary expansion with infinitely many positive coefficients $s_{t}$. Let $S$ be the set of positive integers. The desired set-function $F$ of type 2 on $S$ is defined as follows. If $1 \leq t_{1} \neq t_{2}<\omega$, then

$$
\begin{equation*}
\theta \in \mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \quad \text { if and only if } \mathrm{s}_{\mathrm{t}_{1}} \neq \mathrm{s}_{\mathrm{t}_{2}} \tag{4}
\end{equation*}
$$

in the $r$-ary expansion (3) of $\theta$.
Clearly,

$$
\mathrm{m}\left(\mathrm{~F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right)=1-\frac{1}{\mathrm{r}},\right.
$$

and thus F is of order no less than $1-1 / \mathrm{r}$. On the other hand, S does not contain a complete graph of power $\mathrm{r}+1$ that has property $\mathscr{P}$. For if $\mathrm{S}^{\prime}=\left\{\mathrm{t}_{1}, \cdots, \mathrm{t}_{\mathrm{r}+1}\right\}$ and $\left[\mathrm{S}^{\prime}\right]^{2}$ possesses property $\mathscr{P}$, then there exists a $\theta \in(0,1)$ such that

$$
\theta \in \bigcap_{t_{i}, t_{j} \in S^{\prime} ; i \neq j} F\left(\left\{t_{1}, t_{j}\right\}\right)
$$

Therefore, by (4), the numbers $s_{t_{1}}, \cdots, s_{t_{r+1}}$ are all different, which contradicts (3). This establishes the necessity of our condition.

We complete the proof of the theorem by proving not only the sufficiency of our condition but a stronger result as well; namely, we prove that corresponding to each $\mathrm{u}>1-1 / \mathrm{r}$, there exists an integer $\mathrm{k}_{\mathrm{u}}$ such that

$$
\left(\mathrm{k}_{\mathrm{u}}, 2, \mathrm{u}\right) \Rightarrow \mathrm{r}+1
$$

Indeed, let k denote a positive integer, let $\mathrm{S}=\{0,1, \cdots, \mathrm{k}-1\}$, and let F be a setfunction on $S$, of type 2 and of order not less than $u$.

There is no loss of generality in supposing that $m(F(X))=u$ for each $X \in[S]^{2}$. For if $m(F(X)$ ) were greater than $u$ for some of the $X$, we could replace each of the sets $F(X)$ by a subset $F_{1}(X)$, of measure $u$. Clearly, a subset of $[S]^{2}$ having property $\mathscr{P}$ relative to $\mathrm{F}_{1}$ would also have property $\mathscr{P}$ relative to F .

Suppose now that every point $c$ of $(0,1)$ lies in fewer than $u\binom{k}{2}$ of the sets $F(X)$. Then

$$
\sum_{\mathrm{X} \in[\mathrm{~S}]^{2}} \mathrm{~m}(\mathrm{~F}(\mathrm{X}))<\mathrm{u}\binom{\mathrm{k}}{2}
$$

contrary to the hypothesis that F has order at least u . Hence some c lies in at least $u\binom{k}{2}$ of the sets $F(X)$. That is, the graph induced by some $c$ has at least $u\binom{k}{2}$ edges, and of course the number $h$ of its vertices is at most $k$. A special case of a theorem of P. Turán [14; p. 26] asserts that a graph with h vertices and more than $\frac{1}{2}(1+\varepsilon-1 / r) h^{2}$ edges contains a complete $(r+1)$-gon. It follows that the graph induced by c contains a complete ( $\mathrm{r}+1$ )-gon. This completes the proof of Theorem 1.

Let $S$ be the set of natural numbers, and let $F$ be a set-function on $S$, of type 2 and of order at least $u$. For each subset $S^{\prime}$ of $S$, we write

$$
\Pi\left(S^{\prime}\right)=\bigcap_{X \in\left[S^{\prime}\right]^{2}} F(X)
$$

The "if" part of Theorem 1 asserts that if $u>1-1 / r$, then some set $S^{\prime}$ of $r+1$ natural numbers has property $\mathscr{P}$, that is, satisfies the condition $\Pi\left(\mathrm{S}^{\prime}\right) \neq \emptyset$. The question now arises as to what can be said about the measure of $\Pi\left(S^{\prime}\right)$. We prove the following assertion, which provides a sharpening, for the special case $r=2$, of Theorem 1.

THEOREM 1(A). Let S be the set of natural numbers, and let F be a setfunction on S , of type 2 and of order at least $\mathrm{u}(\mathrm{u}>1 / 2)$. Then, for every $\varepsilon>0$, there exists a set $S^{\prime}$ of three natural numbers such that $m\left(\Pi\left(S^{\prime}\right)\right) \geq u(2 u-1)-\varepsilon$.

This result is best possible for some special values of $u$, in the following sense: If $\mathrm{u}=1-1 / \mathrm{k}(\mathrm{k}=3,4, \cdots)$, then there exist set-functions F on S , of order u and of type 2 , such that $\mathrm{m}(\Pi(\mathrm{X})) \leq \mathrm{u}(2 \mathrm{u}-1$ ) for every $\mathrm{X} \subset \mathrm{S}$ with $\overline{\mathrm{X}}=3$.

Remarks. It is obvious that Theorem $1(\mathrm{~A})$ is a generalization of the special case $r=2$ of Theorem 1. We do not know whether the positive part of this result is best possible for other values of $u$. As to the cases $r>2$, we conjecture that if $u>1-1 / r$, then there exists a subset $S^{\prime} \subset S$ with $\overline{\bar{S}}^{\prime}=r+1$ for which

$$
m\left(\Pi\left(S^{\prime}\right)\right) \geq u(2 u-1)(3 u-2) \cdots(r u-(r-1))-\varepsilon .
$$

Here we also know that the result, if true, is best possible for certain special values of $u$.

Before proving Theorem 1(A), we state some well-known results that we shall often use in the sequel (see [5] and [9]).
(5) To each $\varepsilon>0$ and each positive integer r , there corresponds an integer $\mathrm{s}_{0}(\varepsilon, \mathrm{r})$ with the following property. If $\left\{\mathrm{A}_{\mathrm{k}}\right\}\left(1 \leq \mathrm{k} \leq \mathrm{s}_{0}(\varepsilon, \mathrm{r})\right)$ is a family of measurable subsets of $[0,1]$ and if $\mathrm{m}\left(\mathrm{A}_{\mathrm{k}}\right) \geq \mathrm{u}>0$ for all k , then there exist r integers $\mathrm{k}_{1}<\mathrm{k}_{2}<\cdots<\mathrm{k}_{\mathrm{r}} \leq \mathrm{s}_{0}(\varepsilon, \mathrm{r})$ such that

$$
m\left(\bigcap_{i=1}^{r} A_{k_{i}}\right)>u^{r}-\varepsilon .
$$

The following is an easy corollary.
(6) Let $\left\{\mathrm{A}_{\mathrm{k}}\right\}(1 \leq \mathrm{k}<\infty)$ be a sequence of measurable subsets of $[0,1]$, let $\mathrm{m}\left(\mathrm{A}_{\mathrm{k}}\right) \geq \mathrm{u}>0$, and let $\varepsilon>0$. Then, corresponding to each positive integer r , there exists an increasing sequence $\left\{\mathrm{h}_{\mathrm{j}}\right\}$ of integers such that

$$
m\left(\bigcap_{i=1}^{r} A_{k_{i}}\right)>u^{r}-\varepsilon
$$

for every set $\left\{\mathrm{k}_{\mathrm{i}}\right\}(1 \leq \mathrm{i} \leq \mathrm{r})$ taken from $\left\{\mathrm{h}_{\mathrm{j}}\right\}$.
Now we outline the proof of Theorem $1(\mathrm{~A})$. Let S be the set of natural numbers, let F be a set-function on S satisfying the requirements of Theorem 1(A), and let $\varepsilon>0$. Without loss of generality, we may assume that $m(F(X))=u$ for each $\mathrm{X} \in[\mathrm{S}]^{2}$.

First we define a partition

$$
[\mathrm{S}]^{3}=\mathrm{J}_{1} \cup \mathrm{~J}_{2} \cup \mathrm{~J}_{3} \cup \mathrm{~J}_{4}
$$

as follows. For each $\mathrm{X}=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}\right\}\left(\mathrm{t}_{1}<\mathrm{t}_{2}<\mathrm{t}_{3}\right)$ we put

$$
\begin{aligned}
& \mathrm{F}_{1}(\mathrm{X})=\mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \cap \mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{3}\right\}\right), \\
& \mathrm{F}_{2}(\mathrm{X})=\mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{3}\right\}\right) \cap \mathrm{F}\left(\left\{\mathrm{t}_{2}, \mathrm{t}_{3}\right\}\right),
\end{aligned}
$$

and we write

$$
\left\{\begin{array}{l}
X \in J_{1} \text { if } m\left(F_{1}(X)\right)>u^{2}-\varepsilon / 2 \text { and } m\left(F_{2}(X)\right)>u^{2}-\varepsilon / 2  \tag{7}\\
X \in J_{2} \text { if } m\left(F_{1}(X)\right)>u^{2}-\varepsilon / 2 \text { and } m\left(F_{2}(X)\right) \leq u^{2}-\varepsilon / 2 \\
X \in J_{3} \text { if } m\left(F_{1}(X)\right) \leq u^{2}-\varepsilon / 2 \text { and } m\left(F_{2}(X)\right)>u^{2}-\varepsilon / 2 \\
X \in J_{4} \text { if } m\left(F_{1}(X)\right) \leq u^{2}-\varepsilon / 2 \text { and } m\left(F_{2}(X)\right) \leq u^{2}-\varepsilon / 2
\end{array}\right.
$$

If $S_{1} \subset S$ and $\overline{\bar{S}}_{1}=\boldsymbol{N}_{0}$, then $S_{1}$ contains triplets $X_{1}$ and $X_{2}$ such that

$$
\mathrm{m}\left(\mathrm{~F}_{1}\left(\mathrm{X}_{1}\right)\right)>\mathrm{u}^{2}-\varepsilon / 2 \quad \text { and } \quad \mathrm{m}\left(\mathrm{~F}_{2}\left(\mathrm{X}_{2}\right)\right)>\mathrm{u}^{2}-\varepsilon / 2 .
$$

This is so because by (5) (with $r=2$ ) the set $S_{1}$ contains no infinite subset all of whose triplets belong to the classes $J_{i}(i=2,3,4)$.

From Ramsay's theorem (see the beginning of the Introduction) it follows that all triplets of some infinite subset of $S$ belong to $J_{1}$. Let $S^{\prime}=\left\{t_{1}, t_{2}, t_{3}\right\}\left(t_{1}<t_{2}<t_{3}\right)$ be any triplet in $J_{1}$. Then, by the assumption that $m\left(F\left(\left\{t_{1}, t_{2}\right\}\right)\right)=u$ and by the first line of (7),

$$
m\left(\Pi\left(S^{\prime}\right)\right)>u^{2}-\frac{\varepsilon}{2}-\left[u-\left(u^{2}-\frac{\varepsilon}{2}\right)\right]=u(2 u-1)-\varepsilon
$$

This completes the proof of the first part of Theorem 1(A).
Now we prove the "best possible" part of Theorem 1(A). Let $S$ be the set of natural numbers, and for any $\mathrm{k} \geq 3$, consider the k -ary expansion (3) (with k in place of $r$ ) of an arbitrary $\theta \in[0,1]$. Using again the idea of (4), we define $\mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right)$ (for $\left.1 \leq \mathrm{t}_{1} \neq \mathrm{t}_{2}<\omega\right)$ by the rule

$$
\begin{equation*}
\theta \in \mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \quad \text { if and only if } \mathrm{s}_{\mathrm{t}_{1}} \neq \mathrm{s}_{\mathrm{t}_{2}} \tag{8}
\end{equation*}
$$

Clearly, $m\left(F\left(\left\{t_{1}, t_{2}\right\}\right)\right)=u=1-1 / k$. On the other hand, suppose that $X \in[S]^{3}$, $\mathrm{X}=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}\right\} \quad\left(\mathrm{t}_{1}<\mathrm{t}_{2}<\mathrm{t}_{3}\right)$. From well-known properties of the expansion (3) and from (8) it follows that

$$
m(\Pi(X))=\frac{k(k-1)(k-2)}{k^{3}}=(1-1 / k)(1-2 / k)=u(2 u-1)
$$

This completes the proof of Theorem 1(A).
THEOREM 1(B).

$$
\left(\boldsymbol{N}_{0}, 2,>1-\frac{1}{r}\right) \nRightarrow \mathrm{r}+1 \quad 2 \leq \mathrm{r}<\omega
$$

We only outline the proof. First we establish the following result.
(9) Let S be the set of natural numbers. Corresponding to each pair $\mathrm{t}_{1}, \mathrm{t}_{2}$ $\left(1 \leq \mathrm{t}_{1} \neq \mathrm{t}_{2}<\omega\right)$ and each $\varepsilon>0$, one can define a set function $\mathrm{F}\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}$ on S , of type 2 and satisfying the following conditions:
(a) $\Pi(\mathrm{Z})=\emptyset$ for every $\mathrm{Z} \in[\mathrm{S}]^{\mathrm{r}+1}$,
(b) $m\left(F_{\left\{t_{1}, t_{2}\right\}}(X)\right)=1-\frac{1}{r}$ for every $\mathrm{X} \in[\mathrm{S}]^{2}$ except $\mathrm{X}=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}$,
(c) $\operatorname{m}\left(\mathrm{F}_{\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right)\right)>1-\varepsilon$.

This can be proved, by a slight modification of the construction used in the proof of Theorem 1, as follows.

Let $\ell$ be an integer, put $\mathrm{k}=\ell \mathrm{r}$, and for any $\theta \in[0,1]$, let

$$
\theta=\sum_{\mathrm{t}=1}^{\infty} \frac{\tau_{\mathrm{t}}}{\mathrm{k}^{\mathrm{t}}} \quad\left(0 \leq \tau_{\mathrm{t}}<\mathrm{k}\right)
$$

For $t \in S$ and $i=0, \cdots, r-1$, we now define a set $S_{t, i}$ as follows. If $t \neq t_{1}$ and $t \neq t_{2}$, then $S_{t, i}$ is the set of natural numbers $s$ satisfying the condition $\ell \mathrm{i} \leq \mathrm{s}<\ell(\mathrm{i}+1)$; for the other cases,

$$
\begin{aligned}
& S_{t_{1,0}}=\{0,1, \cdots,(\ell-1) r\}, \\
& S_{t_{1, i}}=\{(\ell-1) r+i\} \quad \text { for } i=1, \cdots, r-1, \\
& S_{t_{2, i}}=\{i\} \quad \text { for } i=0, \cdots, r-2,
\end{aligned}
$$

$$
S_{t_{2}, r-1}=\{r-1, \cdots, \ell r-1\}
$$

Now we define $\mathrm{F}\left(\left\{\mathrm{t}, \mathrm{t}^{\prime}\right\}\right)$ for $1 \leq \mathrm{t} \neq \mathrm{t}^{\prime}<\omega$ by the stipulation that $\theta \in \mathrm{F}\left(\left\{\mathrm{t}, \mathrm{t}^{\prime}\right\}\right)$ if and only if $s_{t}$ and $s_{t^{\prime}}$ belong to sets $\mathrm{s}_{\mathrm{t}, \mathrm{i}}$ and $\mathrm{S}_{\mathrm{t}^{\prime}, \mathrm{i}^{\prime}}$ with $\mathrm{i} \neq \mathrm{i}^{\prime}$.

F clearly satisfies the requirements (a) and (b) of (9).
On the other hand,

$$
m\left(F_{\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right)\right) \geq \frac{1}{\mathrm{k}^{2}}(\mathrm{k}-\mathrm{r})^{2} \geq 1-\frac{2}{\ell}>1-\varepsilon
$$

if $\ell$ is sufficiently large.
Now let $\left\{\mathrm{X}_{\mathrm{j}}\right\} \quad(\mathrm{j}<\omega)$ be a well-ordering of type $\omega$ of the set $[\mathrm{S}]^{2}$. It follows from (9) that, corresponding to every $\mathrm{j}<\omega$, there exists a set-function $\mathrm{F}_{\mathrm{X}_{\mathrm{j}}}$ on S that satisfies the following conditions:

$$
\begin{equation*}
F_{X_{j}}(X) \subset\left(2^{-j-1}, 2^{-j}\right) \quad \text { for every } X \in[S]^{2} \tag{10}
\end{equation*}
$$

the set $\Pi(Z)$ (defined with respect to $\mathrm{F}_{\mathrm{X}_{\mathrm{j}}}$ ) is empty for every $\mathrm{Z} \in[\mathrm{S}]^{\mathrm{r}+1}$;

$$
\begin{aligned}
& m\left(F_{X_{j}}(X)\right)=\left(1-\frac{1}{r}\right) 2^{-j-1} \text { for every } X \in[X]^{2} \text { except } X_{j} \\
& m\left(F_{X_{j}}\left(X_{j}\right)\right)>(1-\varepsilon) 2^{-j-1}
\end{aligned}
$$

Next we define the set-function $F$ on $S$, of type 2, by the condition

$$
\begin{equation*}
F(X)=\bigcup_{j<\omega} F_{X_{j}}(X) \quad \text { for every } X \in[S]^{2} \tag{11}
\end{equation*}
$$

We easily see from (10) and (11) that $\Pi(Z)=\emptyset$ for every $X \in[S]^{r+1}$, and that

$$
m\left(F\left(X_{j}\right)\right)=1-\frac{1}{r}+\left(\frac{1}{r}-\varepsilon\right) 2^{-j-1}>1-\frac{1}{r}
$$

if $\varepsilon<\frac{1}{r}$. Hence $F$ is of order greater than $1-\frac{1}{r}$, and this proves Theorem 1(B). The idea of the proof is partly due to J. Czipszer.

Let $m_{j}=m\left(F\left(X_{j}\right)\right)-\left(1-\frac{1}{r}\right)$ for $j<\omega$, and write $m=\Sigma_{j=0}^{\infty} m_{j}$. In the case of the example just constructed, $m>1 / r-\varepsilon$. We do not know how far this inequality can be improved; we only have some special results which show that if $m$ is sufficiently large for a set-function $F$ on $S$, of type 2 and of order greater than $1-1 / r$, then there always exists a complete $(\mathrm{r}+1)$-gon with the property $\mathscr{P}$. We omit the proof of this, and we only mention that questions of this type lead to interesting problems in measure theory.

THEOREM 2. If u is positive, then $\left(\boldsymbol{\aleph}_{0}, \mathrm{u}\right) \Rightarrow\left(\mathrm{r}, \boldsymbol{\aleph}_{0}\right)$ for each nonnegative integer r .

Proof. We are given a set S with cardinality $\boldsymbol{\aleph}_{0}$. Without loss of generality we suppose that $S=\{t \mid t<\omega\}$. Let $F$ be a set-function on $S$, of type 2 and of order at
least $u$. We shall prove that, in fact, to each $r$ and $u(u>0)$, there corresponds an integer $s=s(u, r)$ with the following property. Amongst any $s$ integers $t_{1}, \cdots, t_{s}$, there exist $r$ integers $t_{i_{1}}, \cdots, t_{i_{r}}$ such that an infinite subset $S^{\prime}$ of S exists for which $\left[\left\{\mathrm{t}_{\mathrm{i}_{1}}, \cdots, \mathrm{t}_{\mathrm{i}_{\mathrm{r}}}\right\}, \mathrm{S}^{\prime}\right]$ possesses property $\mathscr{P}$.

If $s$ is a positive integer, we let $Z=\left\{t_{1}, \cdots, t_{s}\right\}$, and for some $t$ not in $Z$, we consider the sets $\mathrm{F}\left(\left\{\mathrm{t}_{\mathrm{i}}, \mathrm{t}\right\}\right)(1 \leq \mathrm{i} \leq \mathrm{s})$. Let $\delta$ be a positive number less than $\mathrm{u}^{\mathrm{r}}$. It follows from (5) that if $s$ is sufficiently large, say $s>s_{0}\left(u^{r}-\delta, r\right)$, then there exist $r$ vertices $t_{i_{1}}, \cdots, t_{i_{r}}$ among the $t_{i}$ for which

$$
m=m\left(\bigcap_{j=1}^{r} F\left(\left\{t_{i_{j}}, t\right\}\right)\right)>\delta
$$

Since there are infinitely many $t \notin Z$ but only $\binom{\mathrm{s}}{\mathrm{r}}$ possible choices of indices $i_{1}, \cdots, i_{r}$, some set of indices, say $\left\{i_{1}, \cdots, i_{r}\right\}$, corresponds to infinitely many $t$. Denote this set of $t^{\prime}$ s by $S^{\prime \prime}$. Then $S^{\prime \prime}$ is a subset of $S$ of power $\boldsymbol{N}_{0}$.

Let

$$
E_{t}=\bigcap_{j=1}^{r} F\left(\left\{t_{i j}, t\right\}\right) \quad\left(t \in S^{\prime \prime}\right)
$$

Since $m\left(E_{t}\right)>\delta$, the theorem proved in the Introduction guarantees the existence of a denumerable subset $S^{\prime}$ such that

$$
\bigcap_{t \in S^{\prime}} E_{t} \neq \emptyset
$$

But this means that $\left[\left\{\mathrm{t}_{\mathrm{i}_{1}}, \cdots, \mathrm{t}_{\mathrm{i}_{\mathrm{r}}}\right\}, \mathrm{S}^{\prime}\right]$ has property $\mathscr{P}$. This proves Theorem 2.
The question may now be asked: if $u$ is positive, is the statement

$$
\left(\boldsymbol{\aleph}_{0}, \mathrm{u}\right) \Rightarrow\left(\boldsymbol{\aleph}_{0}, \boldsymbol{\aleph}_{0}\right)
$$

true? We were not, in general, able to answer this question, which is one of the most interesting unsolved problems of our paper. We describe a simple example by means of which $J$. Czipszer showed that the answer is negative if $u<1 / 2$. Let $S$ be the set of natural numbers, and let $2 \leq \mathrm{r}<\omega$. Czipszer defined a set-function $\mathrm{F}_{\mathrm{r}}^{*}$ of type 2 on S as follows. If $\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)$ is any pair with $1 \leq \mathrm{t}_{1}<\mathrm{t}_{2}<\omega$, and if $\left\{\mathrm{s}_{t}\right\}$ denotes the sequence of digits in the nonterminating r -ary expansion of a number $\theta$ in $(0,1]$, then

$$
\begin{equation*}
\theta \in \mathrm{F}_{\mathrm{r}}^{*}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \quad \text { if and only if } \mathrm{s}_{\mathrm{t}_{1}}>\mathrm{s}_{\mathrm{t}_{2}} . \tag{12}
\end{equation*}
$$

Clearly, $m\left(F_{r}^{*}(X)\right)=\frac{1}{2}\left(1-\frac{1}{\mathrm{r}}\right)$; hence $\mathrm{F}_{\mathrm{r}}^{*}$ is of order at least $\frac{1}{2}\left(1-\frac{1}{\mathrm{r}}\right)$. Since $\frac{1}{2}\left(1-\frac{1}{\mathrm{r}}\right) \rightarrow \frac{1}{2}$, we only need to show that if $\mathrm{S}^{\prime}$, $\mathrm{S}^{\prime \prime}$ are disjoint infinite subsets of S , then $\left[\mathrm{S}^{\prime}, \mathrm{S}^{\prime \prime}\right]$ does not possess property $\mathscr{P}$ with respect to $\mathrm{F}_{\mathrm{r}}^{*}$ for $2 \leq \mathrm{r}<\omega$. In
fact, if $S^{\prime}$ and $S^{\prime \prime}$ are disjoint infinite subsets of $S$, then there exists an infinite increasing sequence $\left\{t_{k}\right\}$ of natural numbers such that $t_{k} \in S^{\prime}$ if $k$ is odd and $\mathrm{t}_{\mathrm{k}} \in \mathrm{S}^{\prime \prime}$ if k is even, and $\left[\mathrm{S}^{\prime}, \mathrm{S}^{\prime \prime}\right]$ does not possess property $\mathscr{P}$ with respect to $\mathrm{F}_{\mathrm{r}}^{*}$ since the set of edges $\left\{\mathrm{t}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}+1}\right\}(1 \leq \mathrm{i} \leq \mathrm{k})$ also fails to possess property $\mathscr{P}$ for $\mathrm{k} \geq \mathrm{r}$.

Czipszer's example leads to some interesting new questions. First we need some definitions.

Let S be the set of natural numbers, let $\mathrm{T}_{\mathrm{r}}=\left\{\mathrm{t}_{1}, \cdots, \mathrm{t}_{\mathrm{r}+1}\right\}$ be a sequence of $\mathrm{r}+1$ natural numbers, and let $\mathrm{T}_{\infty}=\left\{\mathrm{t}_{1}, \cdots, \mathrm{t}_{\mathrm{r}}, \cdots\right\}$ be an infinite sequence of different natural numbers. Put

$$
\mathrm{J}_{\mathrm{r}+1}=\left\{\left\{\mathrm{t}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}+1}\right\}\right\} \quad(1 \leq \mathrm{i} \leq \mathrm{r}), \quad \mathrm{J}_{\infty}=\left\{\left\{\mathrm{t}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}+1}\right\}\right\} \quad(1 \leq \mathrm{i} \leq \omega) .
$$

Further, let $F$ be a set-function defined on $S$, of type 2 and of order at least $u$. We briefly say that S contains a path $\mathrm{J}_{r+1}$ of length $\mathrm{r}+1$ (with property $\mathscr{P}$ ) or an infinite path $J_{\infty}$ (with property $\mathscr{P}$ ) if there exists a $\mathrm{T}_{\mathrm{r}}$ or a $\mathrm{T}_{\infty}$ such that the corresponding sets $J_{r+1}$ or $J_{\infty}$ possess property $\mathscr{P}$ (with respect to $F$ ), respectively. If in addition the sequences $\mathrm{T}_{\mathrm{r}}$ or $\mathrm{T}_{\infty}$ are increasing, we say that S contains an increasing path of length $r+1$ or an increasing infinite path, respectively. We do not know under what conditions on $u$ the set $S$ contains an infinite path. Perhaps this is the simplest unsolved problem in our paper.

Now Czipszer's set-functions $F_{r}^{*}$ show that for $u<1 / 2$ the set $S$ need not contain an infinite increasing path, and more generally, that with respect to a setfunction of type 2 and order at least $\frac{1}{2}\left(1-\frac{1}{r}\right)$, $S$ need not contain an increasing path of length $r+1$. The question arises whether this is best possible in $u$. It may be true that if $u \geq 1 / 2$ then there exists an infinite increasing path, or that if $\mathrm{u}>\frac{1}{2}\left(1-\frac{1}{\mathrm{r}}\right)$ then there exists an increasing path of length $\mathrm{r}+1$, respectively. We can prove this only for $r=2$.

The character of a problem concerning increasing paths is somewhat different from that of the problems treated so far in our paper; for the problem is meaningful only if the basic set $S$ is an ordered set, and the answer depends not only on the power of S , but also on its order type.

Now we give our result concerning the case $r=2$.
THEOREM 3. Let S be the set of natural numbers, and let F be a set-function defined on S , of type 2 and of order at least u . If $\mathrm{u}>1 / 4$, then there exists an increasing path $\mathrm{I}_{3}$ with property $\mathscr{P}$. For $\mathrm{u} \leq 1 / 4$, this is not necessarily true.

We do not know what happens in case F is merely required to be of order greater than $1 / 4$.

Proof. The negative part of our theorem is shown by the set-function $\mathrm{F}_{2}^{*}$ defined in (12). Consider now a set-function satisfying the requirements of Theorem 3.

For $\mathrm{t}=1,2, \cdots$, define

$$
\begin{equation*}
E_{t}=\bigcup_{t<t^{\prime}<\omega} F\left(\left\{t, t^{\prime}\right\}\right) \quad \text { and } \quad m_{t}=m\left(E_{t}\right) \tag{13}
\end{equation*}
$$

and let $0<\varepsilon<u-1 / 4$. There exists a real number $m$ and an infinite subset $S^{\prime} \subset S$ such that $\left|m-m_{t}\right|<\varepsilon / 2$ for $t \in S^{\prime}$.

By (5) and (13), there exist $t_{1}$ and $t_{2}\left(1 \leq t_{1}<t_{2}<\omega, t_{1}, t_{2} \in S^{\prime}\right)$ such that

$$
m\left(E_{t_{1}} \cap E_{t_{2}}\right)>m^{2}-\varepsilon / 2
$$

Now $F\left(\left\{t_{1}, t_{2}\right\}\right) \subset E_{t_{1}}$, and $m+\varepsilon / 2<m^{2}-\varepsilon / 2+u$, since $\varepsilon<u-1 / 4<m^{2}-m+u$. Hence

$$
\mathrm{m}\left(\mathrm{~F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \cap \mathrm{E}_{\mathrm{t}_{2}}\right)>0,
$$

and therefore

$$
\mathrm{F}\left(\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\right) \cap \mathrm{E}_{\mathrm{t}_{2}} \neq \phi .
$$

Thus, by (13),

$$
F\left(\left\{t_{1}, t_{2}\right\}\right) \cap F\left(\left\{t_{2}, t_{3}\right\}\right) \neq 0 \text { for some } t_{3}>t_{2} .
$$

By the definition of a path with property $\mathscr{P}$, this completes the proof of Theorem 3.
Theorem 3 implies immediately that each infinite subset $S^{\prime}$ of $S$ contains an increasing path $\mathrm{J}_{3}$. Now there are two kinds of nonincreasing paths $\mathrm{J}_{3}$ : either $t_{2}<t_{1}, t_{3}$, or else $t_{2}>t_{1}, t_{3}$. It follows from (5) that each infinite subset $S^{\prime}$ of $S$ contains nonincreasing paths $J_{3}$ of both kinds, for each $u>0$, and that each infinite subset $S^{\prime}$ of $S$ contains two elements $X, Y \in[S]^{2}$, with $X=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}, \mathrm{Y}=\left\{\mathrm{t}_{3}, \mathrm{t}_{4}\right\}$, and $\mathrm{X} \cap \mathrm{Y}=0$, such that $\mathrm{F}(\mathrm{X}) \cap \mathrm{F}(\mathrm{Y}) \neq \emptyset$ for each prescribed ordering of $\mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}, \mathrm{t}_{4}$. With a partition of $[\mathrm{S}]^{3}$ and $[\mathrm{S}]^{4}$ similar to the partition we used in the proof of Theorem 1(A), we can (by applying Ramsay's theorem) prove the following result.

THEOREM 4. Let S be the set of natural numbers, and let F be a set-function on S , of type 2 and of order at least u with $\mathrm{u}>1 / 4$. Then there exists an infinite subset $\mathrm{S}^{\prime}$ of S such that $\mathrm{F}(\mathrm{X}) \cap \mathrm{F}(\mathrm{Y}) \neq \emptyset$ for every pair $\mathrm{X}, \mathrm{Y} \in[\mathrm{S}]^{2}$. The condition $\mathrm{u}>1 / 4$ is necessary.

We omit the proof.
Here we may ask the following question. Let $S$ again be the set of natural numbers, and let a system $\mathrm{Z} \subset[\mathrm{S}]^{2}$ of edges be called independent if $\mathrm{X} \cap \mathrm{Y}=\emptyset$ for every pair $X \neq Y(X, Y \in Z)$. Is it true that if $F$ is a set-function on $S$, of type 2 and of order at least $u(u>0)$, then $S$ contains an infinite subset $S^{\prime}$ such that each independent system $\mathrm{Z} \subset\left[\mathrm{S}^{\prime}\right]^{2}$ possesses property $\mathscr{P}$ ?

We know that there always exists an infinite subset $S^{\prime}$ satisfying the weaker condition that every independent system $\mathrm{Z} \subset[\mathrm{S}]^{2}$ of edges possesses property $\mathscr{P}$ provided $\mathrm{Z} \leq 3$. This can be shown similarly to Theorem 4 .

## 4. THE ABSTRACT CASE

In this section, S always denotes the set of natural numbers.
We say that F is an abstract set-function of type 2, provided F associates with each $\mathrm{X} \in[\mathrm{S}]^{2}$ a subset $\mathrm{F}(\mathrm{X})$ of a fixed set H , and that F possesses property $\mathscr{A}(\mathrm{k})$ if

$$
\bigcap_{i=1}^{k} F\left(X_{i}\right) \neq \emptyset
$$

for every sequence $\left\{\mathrm{X}_{\mathrm{i}}\right\}(1 \leq \mathrm{i} \leq \mathrm{k})$ in $[\mathrm{S}]^{2}$.
A set-function $F$ of type 2 and of order at least $u(u>1-1 / k)$ obviously is an abstract set-function with property $\mathscr{A}(\mathrm{k})$. The following result shows that in the positive theorems proved in Section 3, the assumption that $F$ is of order at least $u$ ( $u>1-1 / k$ ) can not be replaced by the corresponding assumption that $F$ possesses property $\mathscr{A}(\mathrm{k})$. However, some weaker results hold. We state two of them without proof.

THEOREM 5. (a) Suppose that F is an abstract set function with property $\mathscr{A}(\mathrm{k})$ for some $\mathrm{k}(3 \leq \mathrm{k}<\omega)$. Then there exists an infinite subset $\mathrm{S}^{\prime}$ of S such that each nonincreasing path $\mathrm{I}_{3} \subset\left[\mathrm{~S}^{\prime}\right]^{2}$ has property $\mathscr{P}$.
(b) There exists an abstract set-function F, possessing property $\mathscr{A}(3)$, such that no increasing path $\mathrm{I}_{3}$ of S has property $\mathscr{P}$ with respect to F .

We shall now describe some graph-theoretic constructions suggested by these considerations. Let $\mathscr{G}$ be a graph, and let G denote the set of vertices of $\mathscr{G}$. A subset $\mathrm{G}^{\prime}$ of G is said to be a free subset of $\mathscr{G}$ if no two vertices belonging to $\mathrm{G}^{\prime}$ are connected by an edge in $\mathscr{G}$. The graph $\mathscr{G}$ is said to have chromatic number n provided n is the least cardinal number such that G is the sum of n free subsets.

A well-known result of Tutte [2] states that if $n$ is an integer, then there exists a finite graph $\mathscr{G}$ that contains no triangle and has chromatic number n. Several other authors have constructed such graphs and have given estimates for the minimal number of vertices of $\mathscr{G}$ (see [4, p. 346] and [11]). In our next theorem, we shall give a construction for such graphs that we believe to be simpler than the previous ones; unfortunately, it does not give a very good estimate for the minimal number of vertices of $\mathscr{G}$.

It is sufficient to construct a graph $\mathscr{G}$ that has chromatic number $\mathcal{N}_{0}$ and contains no triangle, since, by a theorem of N. G. de Bruijn and P. Erdös (see [1]), if every finite subgraph of a graph $\mathscr{G}$ is r-chromatic, then $\mathscr{G}$ is also r-chromatic. (In place of this argument, we could also use Ramsay's theorem.)

THEOREM 6. Let $\mathrm{G}=[\mathrm{S}]^{2}(\mathrm{~S}=\{1,2, \cdots\})$, and let the graph $\mathscr{G}$ with the set G of vertices be defined by the rule that two distinct vertices $\mathrm{X}=\left\{\mathrm{s}_{1}, \mathrm{~s}_{2}\right\}$ and $\mathrm{Y}=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}\left(1 \leq \mathrm{s}_{1}<\mathrm{s}_{2}<\omega ; 1 \leq \mathrm{t}_{1}<\mathrm{t}_{2}<\omega\right)$ are connected if and only if either $\mathrm{s}_{2}=\mathrm{t}_{1}$ or $\mathrm{t}_{2}=\mathrm{s}_{1}$. Then $\mathscr{G}$ contains no triangle, and its chromatic number is $\boldsymbol{\aleph}_{0}$.

Proof. The first statement is trivial. Suppose that the second is false. Then $\mathrm{G}=\mathrm{G}_{1} \cup \cdots \cup \mathrm{G}_{\mathrm{k}}$, where k is finite and $\mathrm{G}_{1}, \cdots, \mathrm{G}_{\mathrm{k}}$ are free sets in $\mathscr{G}$. Considering that $G=[S]^{2}$, we see from Ramsay's theorem that there exists an $S^{\prime} \subset S$ $\left(\overline{\bar{S}}{ }^{\prime}=\boldsymbol{N}_{0}>3\right)$ such that $\left[S^{\prime}\right]^{2} \subset G_{i}$ for some i $(1<i<k)$. Let $t_{1}, t_{2}, t_{3} \in S^{\prime}$. Then $\mathrm{X}=\left\{\mathrm{t}_{1}, \mathrm{t}_{2}\right\}, \mathrm{Y}=\left\{\mathrm{t}_{2}, \mathrm{t}_{3}\right\} \in \mathrm{G}_{\mathrm{i}}$, and X and Y are connected in $\mathscr{G}$, contrary to the assumption that $G_{i}$ is a free set. This completes the proof of Theorem 6.

Generalizing Tutte's theorem, P. Erdös and R. Rado proved [8, p. 445] that if $n$ is an infinite cardinal number, then there exists a graph $\mathscr{G}$ that contains no triangle and has chromatic number $n$. Moreover, the graph constructed by them has $n$ vertices. Their construction is not quite simple. Using the same idea as in the proof of Theorem 6 and applying a generalization of Ramsay's theorem, we can now give a very simple proof for a part of this result. Namely, we can similarly construct a graph $\mathscr{G}$ that contains no triangle and has chromatic number $n$; but the set of vertices of this graph is of power greater than $n$.
P. Erdös proved [3, p. 34-35] the following generalization of Tutte's theorem. If k and n are positive integers, then there exists a graph $\mathscr{G}$, of chromatic number at least $n$, that contains no circuit of length i for $3 \leq \mathrm{i}<\mathrm{k}$.

One could have believed that, in analogy with Tutte's theorem, this theorem also could be generalized for $\mathrm{n}>\boldsymbol{\aleph}_{0}$. Surprisingly, this is not so:

If a graph $\mathscr{G}$ contains no circuit of length 4 , then its chromatic number is at most $\boldsymbol{\aleph}_{0}$.

We shall publish the proof of this theorem in a forthcoming paper in which we shall also try to determine what kinds of subgraphs a graph $\mathscr{G}$ of chromatic number greater than $\boldsymbol{\aleph}_{0}$ must contain. A typical result: $\mathscr{G}$ must contain an infinite path and an even graph $\left[\mathrm{S}_{0}, \mathrm{~S}_{1}\right]$, where $\overline{\overline{\mathrm{S}}}_{0}=\mathrm{r}, \overline{\overline{\mathrm{S}}}_{1}=\boldsymbol{\aleph}_{1}$.

On the other hand, we prove the following generalization of the theorem of Erdös and Rado cited above.

THEOREM 7. Let k be a positive integer, and let n be an infinite cardinal number. Then there exists a graph $\mathscr{G}$ that has chromatic number at least n and contains no circuit of length $2 \mathrm{i}+1$ for $1 \leq \mathrm{i} \leq \mathrm{k}$.

In our construction, the set of vertices of $\mathscr{G}$ is of power greater than n . We do not know whether there exist such graphs $\mathscr{G}$ with $\overline{\overline{\mathrm{G}}}=\mathrm{n}$. (Added in proof: Recently, we proved that such graphs exist for every n.)

We only outline the proof of Theorem 7. Let $m$ be a cardinal number greater than n , and let $\phi$ denote the initial number of m . To define $\mathscr{G}$, we put $\mathrm{Z}=\{\nu\}$ $(\nu<\phi)$ and $\mathrm{G}=[\mathrm{Z}]^{\mathrm{k}+1}$, and for arbitrary different elements

$$
\begin{gathered}
\mathrm{X}=\left\{\nu_{1}, \cdots, \nu_{\mathrm{k}+1}\right\} \quad \text { and } \mathrm{Y}=\left\{\mu_{1}, \cdots, \mu_{\mathrm{k}+1}\right\} \\
\left(\nu_{1}<\cdots<\nu_{\mathrm{k}+1} ; \mu_{1}<\cdots<\mu_{\mathrm{k}+1}\right)
\end{gathered}
$$

of G , we let X and Y be connected in $\mathscr{G}$ if and only if either

$$
\nu_{2}=\mu_{1}, \nu_{3}=\mu_{2}, \cdots, \nu_{\mathrm{k}+1}=\mu_{\mathrm{k}}
$$

or

$$
\mu_{2}=\nu_{1}, \mu_{3}=\nu_{2}, \cdots, \mu_{\mathrm{k}+1}=\nu_{\mathrm{k}} .
$$

The fact that $\mathscr{G}$ contains no circuit of length $2 i+1$ for $1 \leq i \leq k$ is assured by a simple and essentially finite combinatorial theorem, which we omit.

Suppose now that the chromatic number of $\mathscr{G}$ is less than n . Then $\mathrm{G}=\bigcup_{\alpha<\psi} \mathrm{G}_{\alpha}$, where $\bar{\psi}<\mathrm{n}$ and where $\mathrm{G}_{\alpha}$ is a free subset of $\mathscr{G}$ for every $\alpha<\psi$. If m is chosen to be greater than

then, as a corollary of a generalization of Ramsay's theorem that was proved by P. Erdös and R. Rado (see [7, p. 567]), there exist a subset $S^{\prime}$ of $S^{\prime} \overline{S^{\prime}}=k+2$ ) and an $\alpha<\phi$ such that $\left[\mathrm{S}^{\prime}\right]^{\mathrm{k}+1} \subset \mathrm{G}_{\alpha}$.

Let $\mathrm{S}^{\prime}=\left\{\nu_{1}, \cdots, \nu_{\mathrm{k}+1}, \nu_{\mathrm{k}+2}\right\} \quad\left(\nu_{1}<\cdots<\nu_{\mathrm{k}+2}\right)$. Then

$$
\mathrm{X}=\left\{\nu_{1}, \cdots, \nu_{\mathrm{k}+1}\right\}, \mathrm{Y}=\left\{\nu_{2}, \cdots, \nu_{\mathrm{k}+2}\right\} \in \mathrm{G}_{\alpha},
$$

and $\mathrm{X}, \mathrm{Y}$ are connected in $\mathscr{G}$. This contradicts the assumption that $\mathrm{G}_{\alpha}$ is free.

$$
\text { 5. THE CASE } \mathrm{m}=\boldsymbol{\kappa}_{1} \text { OR } \mathrm{m}=2^{\boldsymbol{N}_{0}}
$$

In this section we shall often refer to the partition symbol $m \rightarrow\left(b_{\nu}\right)_{c}^{r}$ introduced by P. Erdös and R. Rado [6, p. 428]. For the convenience of the reader we restate the definition.

Let $m$ and $c(c \geq 2)$ be cardinal numbers, let $r$ be an integer ( $r \geq 1$ ), let $\phi$ denote the initial number of c , and let $\left(\mathrm{b}_{\nu}\right)(\nu<\phi)$ be a sequence of type $\phi$ of cardinal numbers.

The implication $\mathrm{m} \rightarrow\left(\mathrm{b}_{\nu}\right)_{\mathrm{c}}^{r}$ means that if S is a set of power m and $\left(\mathrm{J}_{\nu}\right)(\nu<\phi)$ is a partition of the set $[\mathrm{S}]^{\mathrm{r}}$ (that is, $[\mathrm{S}]^{\mathrm{r}}=\bigcup_{\nu<\phi} \mathrm{J}_{\nu}$ ), then there exist a subset $\mathrm{S}^{\prime}$ of S and a $\nu_{0}<\phi$ such that $\overline{\overline{\mathrm{S}}}^{\prime}=\mathrm{b}_{\nu_{0}}$ and $\left[\mathrm{S}^{\prime}\right]^{r} \subset \mathrm{~J}_{\nu_{0}}$. The expression $\mathrm{m} \nrightarrow\left(\mathrm{b}_{\nu}\right)_{\mathrm{c}}^{r}$ means that the above statement is false.

Several results concerning the symbolic statement $m \rightarrow\left(b_{\nu}\right)_{c}^{r}$ are proved in [6] and [7]. A forthcoming paper by P. Erdös, A. Hajnal, and R. Rado [5] will contain an almost complete discussion of the symbol.

Note that the problem of proving that $m \rightarrow\left(b_{\nu}\right)_{\mathrm{c}}^{\mathrm{r}}$ is a generalization of the problem settled by Ramsay's theorem. Indeed, Ramsay's theorem (see Section 1) asserts that if c is finite, then $\boldsymbol{\aleph}_{0} \rightarrow\left(\boldsymbol{\aleph}_{0}, \cdots, \boldsymbol{\aleph}_{0}\right)_{\mathrm{c}}^{\mathrm{r}}$ (or, more precisely, that $\boldsymbol{\aleph}_{0} \rightarrow\left(\mathrm{~b}_{\nu}\right)_{\mathrm{c}}^{\mathrm{r}}$ provided c is finite and $\mathrm{b}_{\nu}=\boldsymbol{\aleph}_{0}$ for every $\nu<\phi$.)

Now we turn to our original problems. First we prove the following negative result.
(*) THEOREM 8. If S is a set of power $\mathbf{N}^{\boldsymbol{N}_{0}}$, then there exists a set-function F on S , of type 2 and of order at least 1 , such that no $\mathrm{Z}_{1} \subset[\mathrm{~S}]^{2}$ with cardinality greater than $\aleph_{0}$ possesses property $\mathscr{P}$; that is, if $\mathrm{m}=2 \boldsymbol{\aleph}_{0}$, there need not exist a graph that has at least $\boldsymbol{\aleph}_{1}$ vertices and possesses property $\mathscr{P}$.

Proof. Let $\left\{\mathrm{u}_{\nu}\right\}\left(\nu<\omega_{1}\right)$ and $\left\{\mathrm{X}_{\nu}\right\} \quad\left(\nu<\omega_{1}\right)$ be well-orderings of type $\omega_{1}$ of the sets $[0,1]$ and $[S]^{2}$, respectively. For each $\nu<\omega_{1}$, we define

$$
\mathrm{F}\left(\mathrm{X}_{\nu}\right)=\left\{\mathrm{u}_{\mu}\right\} \quad\left(\nu \leq \mu<\omega_{1}\right) .
$$

Since each $\mathrm{F}\left(\mathrm{X}_{\nu}\right)$ has a denumerable complement, $\mathrm{m}\left(\mathrm{F}\left(\mathrm{X}_{\nu}\right)\right)=1$ if $\nu<\omega_{1}$, and thus $F$ is of order at least 1 . On the other hand, the intersection of any $\boldsymbol{\kappa}_{1}$ of the sets $\mathrm{F}\left(\mathrm{X}_{\nu}\right)$ is obviously empty. This completes the proof.

A corollary of Theorem 8 : if $0 \leq u \leq 1$, then $\left(2^{N_{0}}, 2, u\right) \nRightarrow \aleph_{1}$ provided (*) is assumed. Without the generalized continuum hypothesis, we can prove only the following weaker result.

THEOREM 9. If $\mathrm{u} \leq 1 / 2$, then $\left(2^{\aleph_{0}}, 2, \mathrm{u}\right) \nRightarrow \aleph_{1}$.
Proof. Let S be a set of power $2{ }^{\aleph_{0}}$. By a result of Sierpiński [13], there exists a partition of $[\mathrm{S}]^{2}$ such that the statements

$$
[\mathrm{S}]^{2}=\mathrm{J}_{1} \cup \mathrm{~J}_{2}, \quad \mathrm{~J}_{1} \cap \mathrm{~J}_{2}=\emptyset, \quad \mathrm{S}^{\prime} \subset \mathrm{S}, \text { and }\left[\mathrm{S}^{\prime}\right]^{2} \subset \mathrm{~J}_{\mathrm{j}} \quad(\mathrm{j}=1,2)
$$

imply that $\overline{\bar{S}}^{\prime} \leq \boldsymbol{N}_{0}$. (In terms of the partition relations implied by $\mathrm{m} \rightarrow\left(\mathrm{b}_{\nu}\right)_{\mathrm{c}}^{\mathrm{r}}$, this means that $2^{\not \aleph_{0}} \nrightarrow\left(\boldsymbol{\aleph}_{1}, \boldsymbol{\aleph}_{1}\right)^{2}$.

Now we define

$$
F(X)= \begin{cases}(0,1 / 2) & \text { if } X \in J_{1} \\ (1 / 2,1) & \text { if } X \in J_{2}\end{cases}
$$

This set-function obviously satisfies the requirement of our theorem.
If $u>1 / 2$, the argument above is inconclusive. Now, the edges of a complete graph of power $2^{\boldsymbol{N}_{0}}$ can presumably be split into $2^{\boldsymbol{N}_{0}}$ disjoint classes in such a way that each subset of $S$ of power $\aleph_{1}$ contains an edge from each class. This theorem has never been proved, not even for three classes, without the help of the generalized continuum hypothesis $\left(^{*}\right)$. A proof using $\left(^{*}\right)$ is given in [5]. If we could prove the theorem for $r$ classes ( $r>2$ ) without using (*), then by following our proof of Theorem 9 , we could clearly show that for each $\mathrm{r}<\omega$,

$$
\left(2^{\kappa_{0}}, 2,1-1 / \mathrm{r}\right) \nRightarrow \boldsymbol{\kappa}_{1} .
$$

On the other hand, it is easy to see without using $\left(^{*}\right)$ that $\left(2^{\aleph_{0}}, 2,>0\right) \nRightarrow 3$. To prove this, we let $S$ be the interval $[0,1]$, and we let $F(\{x, y\})$ be the open interval ( $x, y$ ). Obviously,

$$
\mathrm{m}(\mathrm{~F}(\{\mathrm{x}, \mathrm{y}\}))=|\mathrm{x}-\mathrm{y}|>0
$$

and no triangle has the property $\mathscr{P}$.
Trees whose longest paths have length at most 2 are unions of stars. It is well known that every complete graph of power $\boldsymbol{\aleph}_{1}$ is a countable sum of trees, in fact, a countable sum of trees that are unions of stars. Thus, if we assume the continuum hypothesis, then we can construct an $F(X)$ such that $m(F(X))>0$ and no graph containing a path of length 3 has property $\mathscr{P}$. For the sake of completeness we remark that if $c=\aleph_{1}$ and $S$ is a set of power $\aleph_{1}$, we can construct by the above remark a set-function on $S$, of positive order and type 2 , so that no graph of power $\boldsymbol{\aleph}_{1}$ and no path of length 3 has property $\mathscr{P}$.

Our only positive result in this section is the next theorem.
THEOREM 10. If u is positive and $\mathrm{m}>\boldsymbol{\aleph}_{0}$, then $(\mathrm{m}, 2, \mathrm{u}) \Rightarrow \boldsymbol{\aleph}_{0}$.

Remark. If $\mathrm{u} \leq 1 / 2$, we know by Theorem 9 that this result is best possible if $\mathrm{m} \leq 2{ }^{\aleph_{0}}$. If we assume $\left(^{*}\right)$, then, by Theorem 8 , Theorem 10 is best possible for each $\mathrm{u} \leq \mathrm{m}$ and each $\mathrm{m} \leq 2{ }^{*}{ }_{0}$.

Proof. It is sufficient to prove that if $u>0$, then $\left(\boldsymbol{\aleph}_{1}, 2, u\right) \Rightarrow \boldsymbol{\aleph}_{0}$.
Let S be a set of power $\boldsymbol{\aleph}_{1}$; without loss of generality, we suppose that $\mathrm{S}=\{\alpha\}$ $\left(\alpha<\omega_{1}\right)$. Let F be a set-function on S , of type 2 and of order at least u . For brevity, we write

$$
\mathrm{F}\left(\left\{\alpha_{1}, \alpha_{2}\right\}\right)=\mathrm{F}_{\alpha_{1}, \alpha_{2}}=\mathrm{F}_{\alpha_{2}, \alpha_{1}}
$$

Let XoY denote the symmetric difference $\mathrm{X} \cup \mathrm{Y}-(\mathrm{X} \cap \mathrm{Y})$ of the sets X and Y. The following theorem is well known (see [10, p. 168]).

THEOREM $\alpha$. There exists a denumerable sequence $\left\{\mathrm{E}_{\mathrm{s}}\right\}(\mathrm{s}<\omega)$ of measurable subsets of $[0,1]$ such that if E is a measurable subset of $[0,1]$, then corresponding to each $\varepsilon>0$ there exists an $\mathrm{s}<\omega$ for which $\mathrm{m}\left(\mathrm{E} \circ \mathrm{E}_{\mathrm{s}}\right)<\varepsilon$.

Applying Theorem $\alpha$, we obtain the following result.
THEOREM $\beta$. There exist an $\alpha_{0}<\omega_{1}$ and a subset $\mathrm{S}_{1}$ of S with cardinality $\aleph_{1}$ such that for each $\alpha$ and $\alpha^{\prime}$ in $\mathrm{S}_{1}$,

$$
\mathrm{m}\left(\mathrm{~F}_{\alpha_{0}, \alpha^{\prime}} \circ \mathrm{F}_{\alpha_{0}, \alpha^{\prime}}\right)<\varepsilon
$$

Suppose now that $\mathrm{S}_{\mathrm{k}} \subset \cdots \subset \mathrm{S}_{1}$ and the elements $\alpha_{0}, \cdots, \alpha_{\mathrm{k}-1}$ are already defined for some $\mathrm{k}(0<\mathrm{k}<\omega)$ in such a way that $\mathrm{S}_{\mathrm{k}}$ has power $\boldsymbol{\aleph}_{1}$. Then, if we apply Theorem $\alpha \mathrm{k}+1$ times, we establish the following result.

THEOREM $\gamma$. There exist an $\alpha_{\mathrm{k}} \in \mathrm{S}_{\mathrm{k}}\left(\alpha_{\mathrm{k}} \neq \alpha_{\mathrm{i}}\right.$ if $\left.\mathrm{i}<\mathrm{k}\right)$ and a subset $\mathrm{S}_{\mathrm{k}+1} \subset \mathrm{~S}_{\mathrm{k}}$ with cardinality $\aleph_{1}$ such that for each $\mathrm{i} \leq \mathrm{k}$ and for each $\alpha$ and $\alpha^{\prime}$ in $\mathrm{S}_{\mathrm{k}+1}$

$$
\mathrm{m}\left(\mathrm{~F}_{\alpha_{\mathrm{i}}, \alpha^{\prime}} \circ \mathrm{F}_{\alpha_{\mathrm{i}}, \alpha^{\prime}}\right)<\varepsilon 2^{-\mathrm{k}-1}
$$

Thus by induction on $\mathrm{k}, \alpha_{\mathrm{k}}$ and $\mathrm{S}_{\mathrm{k}+1}$ are defined for every $\mathrm{k}<\omega$. Now let

$$
G_{k}=\bigcap_{t=k+1}^{\infty} F_{\alpha_{k}, \alpha_{t}}
$$

For each $\mathrm{k}<\omega$, it follows from Theorem $\beta$ and Theorem $\gamma$ that

$$
\mathrm{m}\left(\mathrm{G}_{\mathrm{k}}\right) \geq \mathrm{m}\left(\mathrm{~F}_{\alpha_{\mathrm{k}}, \alpha_{\mathrm{k}+\mathrm{l}}}\right)-\sum_{\mathrm{t}=\mathrm{k}}^{\infty} \varepsilon 2^{-\mathrm{k}-1}
$$

hence, if $0<\varepsilon<\mathrm{u} / 2$, then

$$
\mathrm{m}\left(\mathrm{G}_{\mathrm{k}}\right) \geq \mathrm{u}-\varepsilon>\mathrm{u} / 2
$$

Finally, the theorem proved in the Introduction enables us to conclude that there exists an infinite sequence $\left\{\mathrm{k}_{\mathrm{r}}\right\}(\mathrm{r}<\omega\}$ such that

$$
\bigcap_{\mathrm{r}=0}^{\infty} \mathrm{G}_{\mathrm{k}_{\mathrm{r}}} \neq \emptyset .
$$

Let $\mathrm{S}^{\prime}=\left\{\alpha_{\mathrm{k}_{\mathrm{r}}}\right\} \quad(\mathrm{r}<\omega)$. Then $\mathrm{S}^{\prime}$ has power $\boldsymbol{N}_{0}$, and $\left[\mathrm{S}^{\prime}\right]^{2}$ possesses property $\mathscr{P}$. The proof of Theorem 10 is now complete.

$$
\text { 6. THE CASE } \mathrm{m}=\boldsymbol{N}_{2} \text {. }
$$

Throughout this and the next section we shall assume the generalized continuum hypothesis (*).
${ }^{(*)}$ THEOREM 11. $\left(\boldsymbol{N}_{2}, 2,>0\right) \Rightarrow \boldsymbol{\aleph}_{0}$.
Proof. Let S be a set of power $\boldsymbol{\aleph}_{2}$, and let F be a set-function on S , of type 2 and of positive order. We split the edges of the complete graph S into countably many classes $J_{t}$ by stipulating that $\mathrm{X} \in \mathrm{J}_{\mathrm{t}}$ if and only if for each $\mathrm{t}<\omega$ and each $\mathrm{X} \in[\mathrm{S}]^{2}$

$$
2^{-t-1}<m(F(X)) \leq 2^{-t}
$$

Since the order of $\mathrm{F}(\mathrm{X})$ is positive,

$$
[\mathrm{S}]^{2}=\bigcup_{\mathrm{t}<\omega} \mathrm{J}_{\mathrm{t}} .
$$

It follows from a theorem in [5] that $\boldsymbol{\aleph}_{2} \rightarrow\left(\boldsymbol{\aleph}_{1}, \cdots, \boldsymbol{\aleph}_{1}, \cdots\right)_{\boldsymbol{\kappa}_{0}}^{2}$ (see the definition of $m \rightarrow\left(b_{\nu}\right)_{c}^{r}$ in Section 5). Hence, at least one of the graphs $J_{t}$ contains a complete graph of power $\boldsymbol{N}_{1}$; that is, there exist a subset $\mathrm{S}^{\prime}$ of S of power $\boldsymbol{\aleph}_{1}$ and a $\mathrm{t}_{0}<\omega$ such that $\left[\mathrm{S}^{\prime}\right]^{2} \subset \mathrm{~J}_{\mathrm{t}_{0}}$. Applying Theorem 10 , with $\mathrm{S}^{\prime}$ playing the role of S , we obtain the desired conclusion.

Theorem 11 is probably best possible. In fact, it seems likely that even if we were to assume that the order of $F$ is at least 1, we could not deduce the existence of a complete subgraph of power $\mathfrak{\aleph}_{1}$ that has property $\mathscr{P}$. This question is connected with the following unsolved problem stated in [5].

Let S be a set of power $\boldsymbol{\aleph}_{2}$. Does there exist a partition of the complete graph S into disjoint sets $\mathrm{J}_{\nu}\left(\nu<\omega_{1}\right)$ such that no countable union of $\mathrm{J}_{\nu}$ 's contains a complete graph of power $\aleph_{1}$; that is, such that if $\mathrm{S}^{\prime}$ is a subset of S with cardinality $\boldsymbol{\aleph}_{1}$, then $\left[\mathrm{S}^{\prime}\right]^{2} \cap \mathrm{~J}_{\nu} \neq \emptyset$ for at least $\boldsymbol{\aleph}_{1}$ sets $\mathrm{J}_{\nu}$ ?

Probably such a decomposition exists, but we have been unable to construct one. For the sake of the argument, assume that it exists. Let $\left\{\mathrm{u}_{\nu}\right\} \quad\left(\nu<\omega_{1}\right)$ be a wellordering of type $\omega_{1}$ of the interval $[0,1]$, and define a set-function of type 2 on S by the condition

$$
\mathrm{F}(\mathrm{X})=\left\{\mathrm{u}_{\mu}\right\} \quad\left(\nu<\mu<\omega_{1}\right) \text { for } \mathrm{X} \in[\mathrm{~S}]^{2}
$$

if and only if $\mathrm{X} \in \mathrm{J}_{\nu}$ for each $\nu<\omega_{1}$. Obviously, F is of order at least 1 . Moreover, if $\mathrm{S}^{\prime}$ is a subset of power $\boldsymbol{\aleph}_{1}$ of S , then F assumes $\boldsymbol{\aleph}_{1}$ distinct values on $\left[\mathrm{S}^{\prime}\right]^{2}$; hence, $[\mathrm{S}]^{2}$ does not possess property $\mathscr{P}$.

## 7. THE CASE $\mathrm{m}>\boldsymbol{\aleph}_{2}$.

Under the assumption that $m>\boldsymbol{\aleph}_{2}$, the connection between our problems and measure theory becomes tenuous, and the questions become purely set-theoretical. In this section we shall make heavy use of [5].
(*) THEOREM 12. If $\mathrm{m}=\aleph_{\alpha+1}$ and $\mathrm{cf}(\alpha)>1$, then $(\mathrm{m}, 2,>0) \Rightarrow \aleph_{\alpha}$.
This theorem is a corollary of the following stronger proposition.
(*) THEOREM $12(\mathrm{~A})$. If $\mathrm{m}=\aleph_{\alpha+1}, \operatorname{cf}(\alpha)>1$; and if to each $\mathrm{X} \in[\mathrm{S}]^{2}$ there corresponds a nonempty subset of $[0,1]$, then there exists a subset $\mathrm{S}^{\prime}$ of S with cardinality $\mathfrak{\aleph}_{\alpha}$ and such that $\left[\mathrm{S}^{\prime}\right]^{2}$ possesses property $\mathscr{P}$.

Proof. Let $\left\{u_{\nu}\right\} \quad\left(\nu<\omega_{1}\right)$ be a well-ordering of type $\omega_{1}$ of $[0,1]$. We define a partition of $[\mathrm{S}]^{2}$ into sets $\mathrm{J}_{\nu}\left(\nu<\omega_{1}\right)$ as follows. For each $\mathrm{X} \in[\mathrm{S}]^{2}$ and each $\nu<\omega_{1}, \mathrm{X}$ is in $J_{\nu}$ if and only if $\nu$ is the least ordinal number for which $\mathrm{u}_{\nu} \in \mathrm{F}(\mathrm{X})$.

A theorem of [5] states that, under the hypotheses of Theorem 12 (A),

$$
\boldsymbol{\kappa}_{\alpha+1} \rightarrow\left(\boldsymbol{\kappa}_{\alpha}\right)_{\boldsymbol{\aleph}_{1}}^{2}
$$

The next theorem implies that Theorem $12(\mathrm{~A})$ is best possible even if the complement of each set $F(X)$ consists of one element.
(*) THEOREM 13. If $\mathrm{m}=\boldsymbol{\aleph}_{\beta}$ and if either $\beta$ is of the first kind or $\beta$ is of the second kind and $\boldsymbol{\aleph}_{\mathrm{cf}(\beta)}$ is not an inaccessible cardinal greater than $\boldsymbol{\aleph}_{0}$, then
(a) $\left(\boldsymbol{\aleph}_{\beta}, 2,1\right) \nRightarrow \boldsymbol{\kappa}_{\beta}$ if cf $(\beta) \neq 0$,
(b) for each $\mathrm{u}<1,\left(\boldsymbol{\aleph}_{\beta}, 2, \mathrm{u}\right) \nRightarrow \boldsymbol{\aleph}_{\beta}$ if $\mathrm{cf}(\beta)=0$.

Moreover, in case (a) the desired set-function F can be chosen so that the complement of each $\mathrm{F}(\mathrm{X})$ consists of exactly one element.

Proof. Let S be a set of power $\boldsymbol{\aleph}_{\beta}$, and consider the case (a). A theorem in [5] implies that there exists a partition of $[\mathrm{S}]^{2}$ into disjoint sets $\mathrm{J}_{\nu}\left(\nu<\omega_{1}\right)$ such that if $S^{\prime}$ is a subset of $S$ with cardinality $\aleph_{\beta}$, and if $\nu<\omega_{1}$, then $\left[\mathrm{S}^{\prime}\right]^{2} \cap \mathrm{~J}_{\nu} \neq \emptyset$. We let $\left\{\mathrm{u}_{\nu}\right\} \quad\left(\nu<\omega_{1}\right)$ be a well-ordering of $[0,1]$ of type $\omega_{1}$, and for each $\nu<\omega_{1}$ and each $X \in[S]^{2}$ we define

$$
\mathrm{F}(\mathrm{X})=[0,1]-\left\{\mathrm{u}_{\nu}\right\} \quad \text { if } \mathrm{X} \in \mathrm{~J}_{\nu}
$$

Clearly, the function F has the desired properties.
We now consider case (b). By virtue of Theorem 1, we may suppose that $\beta>0$. Doing so, we choose an increasing sequence $\left\{\beta_{\mathrm{t}}\right\} \quad(\mathrm{t}<\omega)$ of ordinal numbers less than $\beta$ and cofinal with $\beta$, and for each $\mathrm{t}<\omega$ we choose a subset $\mathrm{S}_{\mathrm{t}}$ of S with cardinality $\boldsymbol{\aleph}_{\beta_{\mathrm{t}}}$ so that the $\mathrm{S}_{\mathrm{t}}$ are disjoint and

$$
S=\bigcup_{t<\omega} S_{t}
$$

On the set $\mathrm{S}^{*}=\left\{\mathrm{S}_{\mathrm{t}}\right\}(\mathrm{t}<\omega)$ there exists by Theorem 1 a set-function $\mathrm{F}^{*}$, of type 2 and of order at least $u$, such that if $S^{* \prime}$ is a subset of $S^{*}$ of power $\boldsymbol{\kappa}_{0}$, then $\left[S^{* \prime}\right]^{2}$ does not possess property $\mathscr{P}$ with respect to $\mathrm{F}^{*}$.

For any $\{\mathrm{x}, \mathrm{y}\} \in[\mathrm{S}]^{2}$, suppose that $\mathrm{x} \in \mathrm{S}_{\mathrm{t}_{1}}$ and $\mathrm{y} \in \mathrm{S}_{\mathrm{t}_{2}}$, and define $\mathrm{F}(\{\mathrm{x}, \mathrm{y}\})$ as follows:

$$
\begin{array}{ll}
F(\{x, y\})=(0,1) & \left(t_{1}=t_{2}\right) \\
F(\{x, y\})=F^{*}\left(\left\{S_{t_{1}}, S_{t_{2}}\right\}\right) & \left(t_{1} \neq t_{2}\right)
\end{array}
$$

It is easy to verify that F has the desired properties. This completes the proof.
For the case where $\boldsymbol{\aleph}_{\mathrm{cf}(\beta)}$ is inaccessible and greater than $\boldsymbol{\aleph}_{0}$, the problem remains unsolved.
${ }^{(*)}$ THEOREM 14. If $\mathrm{m}=\boldsymbol{\aleph}_{\beta}>\boldsymbol{\aleph}_{0}$ is a limit cardinal and if $\mathrm{n}<\mathrm{m}$, then $(\mathrm{m}, 2,>0) \Rightarrow \mathrm{n}$.

It is a theorem in [5] that

$$
\mathrm{m} \rightarrow(\mathrm{n})_{\aleph_{1}}^{2}
$$

Both Theorem 12 and Theorem 14 follow from this. Moreover, just as in Theorem 12 (A), instead of assuming that F is of positive order, we can merely assume that $F(X)$ is nonempty for each $X \in[S]^{2}$. We omit the details.

The only cases we have not yet discussed are $\mathrm{m}=\aleph_{\alpha+1}$, where $\alpha>1$ and either $\operatorname{cf}(\alpha)=0$ or $\operatorname{cf}(\alpha)=1$.
(*) THEOREM 15. If $\mathrm{m}=\boldsymbol{\aleph}_{\alpha+1}, \alpha>0, \operatorname{cf}(\alpha)=0$, and $\mathrm{u}>0$, then

$$
(\mathrm{m}, 2, \mathrm{u}) \Rightarrow \aleph_{\alpha}
$$

Proof. Let S be a set of power $\boldsymbol{\aleph}_{\alpha+1}$. Without loss of generality suppose that $S=\{\nu\} \quad\left(\nu<\omega_{\alpha+1}\right)$. Let $F$ be a set-function of $S$, of type 2 and of order at least u . We shall use methods employed in [5].

By the ramification method used there, we know that there exists an increasing sequence $\left\{\nu_{\mu}\right\}\left(\mu<\omega_{\alpha}\right)$ such that if $\mu<\mu^{\prime} \leq \mu^{\prime \prime}<\omega_{\alpha}$, then

$$
\begin{equation*}
\mathbf{F}\left(\left\{\nu_{\mu}, \nu_{\mu^{\prime}}\right\}\right)=\mathbf{F}\left(\left\{\nu_{\mu}, \nu_{\mu}{ }^{\prime \prime}\right\}\right) . \tag{16}
\end{equation*}
$$

We shall write $\mathrm{F}_{\mu}=\mathrm{F}\left(\left\{\nu_{\mu}, \nu_{\mu+1}\right\}\right)$. Let $\left\{\alpha_{\mathrm{t}}\right\} \quad(\mathrm{t}<\omega)$ be an increasing sequence of ordinal numbers less than $\alpha$, cofinal with $\alpha$ and such that $\alpha_{\mathrm{t}}>2$ and $\boldsymbol{\aleph}_{\alpha_{\mathrm{t}}}$ is regular. Since $[0,1]$ has only $\boldsymbol{\aleph}_{2}$ subsets, it follows that corresponding to each $\mathrm{t}<\omega$, there exist a $\mu_{\mathrm{t}}$ and a set $\mathrm{Z}_{\mathrm{t}}$ of ordinal numbers

$$
\mu \quad\left(\omega_{\alpha_{\mathrm{t}-1}}<\mu \leq \omega_{\alpha_{\mathrm{t}}} ; \alpha_{-1}=0\right)
$$

such that $Z_{t}$ has power $\boldsymbol{\kappa}_{\alpha_{t}}$, and $\mathrm{F}_{\mu}=\mathrm{F}_{\mu_{\mathrm{t}}}$ for each $\mu$ in $\mathrm{Z}_{\mathrm{t}}$. If $\mathrm{t}<\omega$, then $\mathrm{m}\left(\mathrm{F}_{\mu_{\mathrm{t}}}\right) \geq \mathrm{u}>0$; therefore, we conclude from the theorem proved in the Introduction that there exists an infinite subsequence $\left\{\mathrm{t}_{\mathrm{s}}\right\}(\mathrm{s}<\omega)$ such that

$$
\bigcap_{s<\omega} F_{\mu_{\mathrm{t}_{\mathrm{s}}}} \neq \emptyset
$$

Let

$$
\mathrm{Z}=\bigcup_{\mathrm{s}<\omega} \mathrm{Z}_{\mathrm{t}_{\mathrm{s}^{\prime}}} \quad \mathrm{S}^{\prime}=\left\{\nu_{\mu}\right\} \quad(\mu \in \mathrm{Z}) .
$$

Clearly,

$$
\overline{\overline{\mathrm{S}}}^{\prime}=\sum_{\mathrm{s}<\omega} \boldsymbol{\aleph}_{\alpha_{\mathrm{t}}}=\boldsymbol{\kappa}_{\alpha},
$$

and, by (16), $\left[\mathrm{S}^{\prime}\right]^{2}$ possesses property $\mathscr{P}$. This completes the proof of the theorem.
We note that under the hypotheses of Theorem $15,(\mathrm{~m}, 2,>0) \nRightarrow \boldsymbol{N}_{\alpha}$. This is true because of a theorem in [5] which states that if $\operatorname{cf}(\alpha)=0$, then

$$
\boldsymbol{\aleph}_{\alpha+1} \nrightarrow\left(\boldsymbol{\aleph}_{\alpha}\right)_{\boldsymbol{\aleph}_{0}}^{2} .
$$

That is, if S is a set of power $\boldsymbol{\kappa}_{\alpha+1}(\operatorname{cf}(\alpha)=0)$, then there exists a partition of $[S]^{2}$ into disjoint sets $J_{t}(t<\omega)$ such that if $t<\omega, S^{\prime} \subset S$, and $\left[S^{\prime}\right]^{2} \subset J_{t}$, then

$$
\overline{\overline{\mathbf{S}}}^{\prime}<\boldsymbol{\aleph}_{\alpha}
$$

For each $\mathrm{X} \epsilon[\mathrm{S}]^{2}$ and each $\mathrm{t}<\omega$, we define $\mathrm{F}(\mathrm{X})=\left(2^{-\mathrm{t}-1}, 2^{-t}\right)$ if $\mathrm{X} \in \mathrm{J}_{\mathrm{t}}$. For this F it is obvious that $(\mathrm{m}, 2,>0) \nRightarrow \boldsymbol{\aleph}_{\alpha}$.
(*) THEOREM 16. If $\mathrm{m}=\boldsymbol{\aleph}_{\alpha+1}, \operatorname{cf}(\alpha)=1$, and $\alpha>1$, then
(a) $(\mathrm{m}, 2,1) \nRightarrow \boldsymbol{\aleph}_{\alpha}$,
(b) $(\mathrm{m}, 2,>0) \Rightarrow \mathrm{n}\left(\mathrm{n}<\boldsymbol{\aleph}_{\alpha}\right)$.

Note that, in harmony with our remarks in the discussion of the case $m=\boldsymbol{N}_{2}$, we do not know whether or not $(\mathrm{m}, 2,1) \nRightarrow \boldsymbol{\aleph}_{\alpha}$ is true if the condition $\alpha>1$ is omitted.

Proof of Theorem 16. The conclusion (b) follows trivially from Theorem 14. To prove (a), we refer to the following theorem in [5]. Let S be a set of power $\boldsymbol{\aleph}_{\alpha+1}$, where $\operatorname{cf}(\alpha)=1$ and $\alpha>1$. Then there exists a partition of $[\mathrm{s}]^{2}$ into disjoint sets $\mathrm{J}_{\nu}\left(\nu<\omega_{1}\right)$ such that if $\mathrm{S}^{\prime}$ is a subset of S of power $\boldsymbol{\aleph}_{\alpha}$, then

$$
\left[\mathrm{S}^{\prime}\right]^{2} \cap \mathrm{~J}_{\nu} \neq \emptyset
$$

for $\aleph_{1}$ sets $\mathrm{J}_{\nu}$.
We now let $\left\{u_{\nu}\right\}\left(\nu<\omega_{1}\right)$ be a well-ordering of type $\omega_{1}$ of the interval [0, 1], and we define a set-function $F$ by the condition that for each $\nu<\omega_{1}$ and each $\mathrm{X} \in[\mathrm{S}]^{2}$,

$$
\mathrm{F}(\mathrm{X})=\left\{\mathrm{u}_{\mu}\right\} \quad\left(\nu<\mu<\omega_{1}\right) \quad \text { if } \mathrm{X} \in \mathrm{~J}_{\nu}
$$

By analogy with the remark made after the proof of Theorem 11, it is easy to see that F has the desired properties.

## 8. THE CASE $\mathrm{k}>2$

We shall discuss this case only briefly. At present we cannot even settle the following question: Is it true that for each $u>0$

$$
\left(\aleph_{1}, 3, \mathrm{u}\right) \Rightarrow 4 ?
$$

Let $\mathrm{k}, \mathrm{m}$, and n be integers. It is an old problem of P. Turán's to determine the smallest integer $f(k, n, m)$ such that if

$$
A_{1}, \cdots, A_{f(k, n, m)}
$$

are k-tuples formed from a set $S$ of $m$ elements, then there always exist $n$ elements of $S$ such that each $k$-tuple of these $n$ elements is an $A_{i}$. As we stated earlier, Turán determined $f(2, n, m)$. For $k>2$, the problem appears to be quite difficult. It is easy to show that

$$
C_{k, n}=\lim _{m \rightarrow \infty} \frac{f(k, n, m)}{m^{k}}
$$

exists. The results of Turán [2] imply that

$$
0<\mathrm{C}_{\mathrm{k}, \mathrm{n}}<\frac{1}{\mathrm{k}!} \quad \text { and } \quad \mathrm{C}_{2, \mathrm{n}}=\frac{1}{2}\left(1-\frac{1}{\mathrm{n}-1}\right) ;
$$

but even the value of $\mathrm{C}_{3,4}$ is not known.
It is easy to deduce by the methods used to prove Theorem 1 that if $u>k!C_{k, n}$, then

$$
\left(\boldsymbol{N}_{0}, \mathrm{k}, \mathrm{u}\right) \Rightarrow \mathrm{n} .
$$

This is no longer true if $u=k!C_{k, n}$.
