## CORRIGENDUM

## Rational approximation on the positive real axis

[Proc. London Math. Soc. (3) 31 (1975) 439-56]
By PAUL ERDÖS and A. R. REDDY
[Received 17 November 1976]
There is an inaccuracy in one of the calculations presented in the proof of Theorem 2 (pp. 443-44). This occurred in equation (20).

By making the following changes throughout the proof:

| $D(n)$ | to $[D(n)]^{\frac{1}{2}}$, |  |
| :--- | ---: | :--- |
| $e_{k+1}(x)$ | to | $e_{2}(x)$, |
| $l_{k}\left(n[D(n)]^{-1}\right)$ | to | $l_{1}\left(n[D(n)]^{-1}\right)$, |
| $l_{k}\left(n e^{2}[D(n)]^{-1}\right)$ | to | $l_{1}\left(n e^{2}[D(n)]^{-\frac{1}{2}}\right)$, |

we get easily the following:
Theorfa A. For every $c>0$ and $k \geqslant 1$ there is an entire function of infinite order with non-negative coefficients for which there exist infinitely many $n$ such that

$$
\lambda_{0, n} \geqslant \exp \left(-\left(n[D(n)]^{-1}\right)\right) .
$$

By careful calculation $\frac{1}{3}$ can be replaced by $\frac{1}{2}-\varepsilon(\varepsilon>0)$.
By adopting an approach used to prove Theorem 15 of [1], one can easily prove the following:

Theorem B. Let $P(x)$ and $Q(x)$ be any polynomials of degrees at most $n$. Then there is a constant $c>0$ for which

$$
\left\|\exp \left(-e^{x}\right)-\frac{P(x)}{Q(x)}\right\|_{\mathrm{I}_{\infty}(0, \infty)} \geqslant \exp \left(\frac{-c n}{\log \log n}\right)
$$

We take this opportunity to correct the following printing errors:

| Page | Line | Should read | For |
| :---: | ---: | :---: | :---: |
| 444 | 13 | $\leqslant$ | $\times$ |
| 449 | -4 | $\rho(<1)$ and regular growth | $\rho$ |
| 450 | 5 | $2 d_{1} d_{2} \ldots d_{n} d_{2 n+1}$ | $2 d_{2 n+1}$ |
| 453 | 11 | $<$ | $\leqslant$ |

# RATIONAL APPROXIMATION ON THE POSITIVE REAL AXIS 

By PAUL ERDÖS and A. R. REDDY

[Received 31 October 1973-Revised 18 June 1974]

## Introduction

Rational Chebyshev approximation to reciprocals of certain entire functions by reciprocals of polynomials on the positive real axis has recently attracted the attention of many mathematicians. By developing certain new methods of approach we successfully attacked ([3]-[6]) some of the related problems. This paper is a continuation of our earlier papers ([3]-[6]). The results of this paper improve and extend some of the earlier results with simplified proofs (ef. Theorem 3). For a reader interested in this topic, this paper may serve as a guide by illustrating some of the techniques (old ones with refinements, as well as new) which we used to solve some of the very interesting and difficult problems of the field (cf. examples 1, 2, 3 of Theorem 5).

## Notation and definitions

Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}$ be any entire function. As usual, let

$$
M(r)=\max _{|\varepsilon|=r}|f(z)|, \quad m(r)=\max _{n \geqslant 1}\left|a_{n}\right| r^{n}=\left|a_{v}\right| r^{\eta}
$$

where $\nu=\nu(r)$ is an increasing function of $r . M(r), m(r)$, and $\nu(r)$ are known as the maximum modulus, maximum term, and the rank of the maximum term, respectively. If there exists more than one term which is equal to the maximum term, then we take the one with the largest index. $S_{n}(z)$ denotes the $n$th partial sum of $f(z) . \pi_{n}$ denotes the class of ordinary polynomials of degree at most $n, \pi_{m, n}$ denotes the class of all rational functions of the form $r_{m, n}=p_{m} / q_{n}$, where $p_{m} \in \pi_{m}, q_{n} \in \pi_{n}$, Throughout our work we denote ( $k \geqslant 1$ ):

$$
\begin{array}{r}
l_{k}(x)=l_{k-1}[\log x], \quad l_{0}(x)=x ; \\
e_{k}(x)=e_{k-1}[\exp x], \quad e_{0}(x)=x ; \\
n\left(l_{1} n\right)\left(l_{2} n\right)\left(l_{3} n\right) \ldots\left(l_{k+1} n\right)^{2}=A(n) ; \\
\left(l_{1} n\right)\left(l_{2} n\right)\left(l_{3} n\right) \ldots\left(l_{k} n\right)^{1+z}=B(n) ; \\
\quad\left(l_{1} n\right)\left(l_{2} n\right)\left(l_{3} n\right) \ldots\left(l_{k} n\right)=D(n) .
\end{array}
$$

As usual we write

$$
\begin{equation*}
\lambda_{0, n}\left(f^{-1}\right) \equiv \lambda_{0, n} \equiv \inf _{p \in \pi_{\mathrm{n}}}\left\|\frac{1}{f(x)}-\frac{1}{p(x)}\right\|_{(0, \infty)}, \tag{1}
\end{equation*}
$$

where $\|\cdot\|$ is the uniform norm on $[0, \infty)$. As usual we define the order $\rho$ of $f(z)$ as follows ([2], p. 8). The entire function $f(z)$ is of order $\rho$ if

$$
\underset{r \rightarrow \infty}{\limsup } \frac{\log \log M(r)}{\log r}=\rho \quad(0 \leqslant \rho \leqslant \infty) .
$$

If $\rho$ is positive and finite, then we define the type $\tau$ and the lower type $\omega$, corresponding to the order $\rho$, as follows:
(2) $\underset{r \rightarrow \infty}{\limsup } r^{-\rho} \log M(r)=\tau, \quad \underset{r \rightarrow \infty}{\liminf } r^{-\rho} \log M(r)=\omega$

$$
(0<\rho<\infty, 0 \leqslant \omega \leqslant \tau \leqslant \infty) .
$$

It is known ([2], p. 13) that for functions of finite order we can replace $\log M(r)$ by $\log m(r)$ in the above formulae. That is,

$$
\limsup _{r \rightarrow \infty} \frac{\log \log m(r)}{\log r}=\rho \quad(0 \leqslant \rho \leqslant \infty),
$$

(2') $\underset{r \rightarrow \infty}{\limsup } r^{-\rho} \log m(r)=\tau, \quad \underset{r \rightarrow \infty}{\liminf r^{-\rho}} \log m(r)=\omega$

$$
(0<\rho<\infty, 0 \leqslant \omega \leqslant \tau \leqslant \infty) .
$$

If $f(z)$ is of order zero, then we define as in [11], p. 145, the logarithmic order $\rho_{l}=\Lambda+1$, and if $\Lambda$ is strictly positive and finite then the corresponding logarithmic types are defined as follows:

$$
\underset{r \rightarrow \infty}{\limsup } \frac{\log \log M(r)}{\log \log r}=\underset{r \rightarrow \infty}{\lim \sup } \frac{\log \log m(r)}{\log \log r}=\Lambda+1 \quad(0 \leqslant \Lambda \leqslant \infty),
$$

$\underset{r \rightarrow \infty}{\limsup } \frac{\log M(r)}{(\log r)^{\Lambda+1}}=\underset{r \rightarrow \infty}{\limsup } \frac{\log m(r)}{(\log r)^{\Lambda+1}}=\tau_{l}$,

$$
\liminf _{r \rightarrow \infty} \frac{\log M(r)}{(\log r)^{A+1}}=\liminf _{r \rightarrow \infty} \frac{\log m(r)}{(\log r)^{\Lambda+1}}=\omega_{l} \quad\left(0<\Lambda<\infty, 0 \leqslant \omega_{l} \leqslant \tau_{l} \leqslant \infty\right) .
$$

It is also known ([20], p. 45) that if $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}$ is of order $\rho(0<\rho<\infty)$, type $\tau$, and lower type $\omega(0<\omega \leqslant \tau<\infty)$, then

$$
\underset{n \rightarrow \infty}{\limsup }(n / \rho e)\left|a_{n}\right|^{\rho / n}=\tau,
$$

and

$$
\begin{equation*}
\liminf _{p \rightarrow \infty}\left(n_{p} / \rho e\right)\left|a_{n_{p}}\right|^{\rho / n_{p}} \geqslant \omega, \tag{3}
\end{equation*}
$$

for a sequence of numbers $n_{p}$ satisfying the condition

$$
\begin{equation*}
\limsup _{p \rightarrow \infty}\left(n_{p+1} / n_{p}\right) \leqslant x_{1} / x_{2}, \tag{4}
\end{equation*}
$$

where $x_{1}$ is the greatest and $x_{2}$ the smallest root of the equation

$$
\begin{equation*}
x \log (x / e)+(\omega / \tau)=0 . \tag{5}
\end{equation*}
$$

Lemma 1 ([7], pp. 534-35). Let $p(x)$ be any algebraic polynomial of degree at most $n$. If this polynomial is bounded by $M$ on an interval of total length $l$ contained in $[-1,1]$, then in $[-1,1]$,

$$
\begin{equation*}
|p(x)| \leqslant M\left|T_{n}\left(4 l^{-1}-1\right)\right| \tag{6}
\end{equation*}
$$

where $2 T_{n}(x)=\left(x+\sqrt{ }\left(x^{2}-1\right)\right)^{n}+\left(x-\sqrt{ }\left(x^{2}-1\right)\right)^{n}$.
Lemma 2 ([20], p. 34). Let $f(z)=\Sigma_{0}^{\infty} a_{1} z^{k}$ be any entire function of finite order $\rho$. Then for any $\varepsilon>0$, and all sufficiently large $r \geqslant r_{0}(\varepsilon)$, we have

$$
M(r) \leqslant m(r) r^{\rho+\tau} .
$$

Lemma 3 ([10], Problem [1], part I). Let

$$
\begin{equation*}
f(x)=1+\sum_{j=1}^{\infty} \frac{x^{\prime}}{d_{1} d_{2} d_{3} \ldots d_{j}} \quad\left(d_{j+1}>d_{j}>0, j \geqslant 1\right) . \tag{7}
\end{equation*}
$$

Then for $x=d_{n}$, the $n$th term of the series (7) becomes the maximum term.
For the detailed discussion of our results, we need the following known results.

Theorem I ([8], Theorem 6). Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}$ be an entire function of order $\rho$, type $\tau$, and lower type $\omega(0<\omega \leqslant \tau<\infty)$, with $a_{0}>0$ and $a_{k} \geqslant 0$ for all $k \geqslant 1$. Then

$$
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n}<1 .
$$

Theorem II ([12], Theorem 7'). Let $f(z)=\Sigma_{k=0}^{0} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0\right.$, $k \geqslant 1$ ) be an entire function satisfying the assumptions that $0<\Lambda<\infty$ and $0<\omega_{1} \leqslant \tau_{i}<\infty$. Then

$$
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{n-1-\alpha / \lambda)}<1 .
$$

Theorem III ([13], Theorem D). Let $f(z)=\sum_{k=0}^{0} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0\right.$, $k \geqslant 1)$ be any entire function of order $\rho(0<\rho<\infty)$, type $\tau$, and lower type $\omega$, with the assumption that $\tau<\theta \omega$ for a $\theta<2$ and $0<\omega \leqslant \tau<\infty$. Then

$$
\liminf _{n \rightarrow 0}\left(\lambda_{0, n}\right)^{1 / n} \geqslant\left(\omega / \tau 2^{2 \rho+1}\right)^{\pi_{1} / \rho x_{1}}
$$

Theorem IV ([3], Theorem 1). Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0\right.$, $k \geqslant 1$ ) be any entire function. Then for each $\varepsilon>0$ there exist infinitely many $n$ such that

$$
\lambda_{0, n} \leqslant \exp \left(-n(\log n)^{-1-9}\right)
$$

Theorem V ([3], Theorem 2). Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}$ be any entire function of infinite order with non-negative coefficients. Then for each $\varepsilon>0$ there exist infinitely many $n$ for which

$$
\lambda_{0, n} \geqslant \exp (-\varepsilon n)
$$

Theorem VI ([18], Theorem). Let $f(x)=e^{x}$. Then

$$
\lim _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n}=\frac{1}{3}
$$

Careful observation of the above theorems naturally leads to the following questions.

Question 1. Can one obtain under the assumptions of Theorem I the fact that

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n}>0 ?
$$

Question 2. Is it possible to improve the upper bound and provide a simple proof to Theorem I ?

Question 3. What conclusion do we get by dropping the assumptions on the logarithmic types in Theorem II?

Question 4. Is it possible to prove Theorem III without the assumption that $\tau<\theta \omega$ ?

Question 5. Is it possible to replace $(\log n)^{1+e}$ by $\left(l_{1} n\right)\left(l_{2} n\right) \ldots\left(l_{k} n\right)^{1+6}$ for any $k \geqslant 1$ in Theorem IV ?

Question 6. Given an $\varepsilon_{n} \geqslant(\log \log n)^{-1}$ can we replace $\varepsilon$ in Theorem V by $\varepsilon_{n}$ ?

Question 7. Are there any other functions besides $e^{x}$ for which we get, for a $\psi(n)$ which tends to infinity,

$$
\lim _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / 4(n)}=\delta \quad(0<\delta<1) ?
$$

These questions motivated the work of this paper and in it we answer all of them.

## New results

Theorem 1. Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0, k \geqslant 1\right)$ be any entire function. Then for each $\varepsilon>0$ and any $k \geqslant 1$, there exist infinitely many $n$ such that

$$
\begin{equation*}
\lambda_{0, n} \leqslant \exp \left(-n /\left(l_{1} n\right)\left(l_{2} n\right) \ldots\left(l_{k} n\right)^{1+e}\right) \tag{8}
\end{equation*}
$$

Proof. If $f(z)=\sum_{0}^{\infty} a_{k} z^{k}$ is entire, then $\lim _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n}=0$. Let $u_{n}=a_{n}^{-1 / n}$. Then $u_{n} \rightarrow \infty$. Now it is easy to observe from the
convergence of

$$
\prod_{j=e_{k}+1(2)}^{\infty}\left(1+[A(j)]^{-1}\right)
$$

that there exist arbitrarily large values of $n$ for which for each $l>0$,

$$
\begin{equation*}
u_{n+1}>u_{n} \prod_{t=1}^{t}\left(1+[A(n+t)]^{-1}\right) \tag{9}
\end{equation*}
$$

From (9) it follows, with $l=n$, that

$$
\begin{equation*}
u_{2 n}>u_{n}\left(I+n[2 A(n)]^{-1}\right) \tag{10}
\end{equation*}
$$

Given any $\varepsilon>0$, we can show now that there exist infinitely many $n$ such that

$$
\begin{equation*}
\left\|\frac{1}{f(x)}-\frac{1}{S_{2 n}(x)}\right\|_{(0, \infty)}<\exp \left(-2 n[B(2 n)]^{-1}\right) \tag{11}
\end{equation*}
$$

By the definition of $\lambda_{0, n}$ (8) follows from (11). To prove (11), observe that, on the one hand, we have for all $x \geqslant 0$,

$$
0 \leqslant \frac{1}{S_{2 n}(x)}-\frac{1}{f(x)} \leqslant \frac{1}{S_{2 n}(x)} \leqslant \frac{1}{a_{n} x^{n}}
$$

Now for any given $\varepsilon>0, \dagger$ let $x \geqslant u_{n}\left(1+[B(n)]^{-1}\right)$. Then

$$
\begin{equation*}
a_{n} x^{n} \geqslant\left(1+[B(n)]^{-1}\right)^{n} \geqslant \exp \left(2 n[B(2 n)]^{-1}\right) \tag{12}
\end{equation*}
$$

On the other hand, let $x<u_{n}\left(1+[B(n)]^{-1}\right)$. Then for all $n \geqslant n_{1}$,

$$
\begin{equation*}
0 \leqslant \frac{1}{S_{2 n}(x)}-\frac{1}{f(x)}=\frac{f(x)-S_{2 n}(x)}{f(x) S_{2 n}(x)} \leqslant a_{0}^{-2} \sum_{k=2 n+1}^{\infty} a_{l c^{2}} x^{k} \tag{13}
\end{equation*}
$$

By (9) and (10), we have for all $k>2 n$,

$$
\begin{equation*}
a_{k}<u_{n}^{-k}\left(1+n[2 A(n)]^{-1}\right)^{-k} \tag{14}
\end{equation*}
$$

Thus, from (13) and (14), for $x<u_{n}\left(1+[B(n)]^{-1}\right.$, we obtain

$$
\begin{equation*}
a_{0}^{-2} \sum_{k=2 n+1}^{\infty} a_{k} x^{k} \leqslant a_{0}^{-2} \sum_{k-2 n+1}^{\infty}\left(\frac{1+[B(n)]^{-1}}{1+n[2 A(n)]^{-1}}\right)^{k} . \tag{15}
\end{equation*}
$$

A simple calculation based on (15) gives us

$$
\begin{equation*}
a_{0}^{-2} \sum_{k=2 n+1}^{\infty} a_{k} x^{k} \leqslant \exp \left(-2 n[B(2 n)]^{-1}\right) \tag{16}
\end{equation*}
$$

Inequality (11) now follows from (12) and (16).
Theorem 2. For every large $c>0$ and $k \geqslant 1$ there is an entire function of infinite order with non-negative coefficients for which there exist infinitely
many $n$ such that

$$
\lambda_{0, n} \geqslant \exp \left(-c n /\left(l_{1} n\right)\left(l_{2} n\right) \ldots\left(l_{k} n\right)\right)
$$

Proof. Let $f(x)=e_{k+1}(x)(k \geqslant 1)$, and let us suppose that for all large $n$,

$$
\begin{equation*}
\left\|\frac{1}{f}-\frac{1}{p}\right\|_{(0, \infty)}<\exp \left(-\operatorname{cn}[D(n)]^{-1}\right) \tag{17}
\end{equation*}
$$

Let $x=l_{k}\left(n[D(n)]^{-1}\right)=r_{1}(k)$, say $(k \geqslant 1)$. At this point

$$
f(x)=e_{k+1}(x)=\exp \left(n[D(n)]^{-1}\right)
$$

Then, by (17),

$$
\begin{equation*}
|p|<\exp \left(2 n[D(n)]^{-1}\right) \tag{18}
\end{equation*}
$$

But at $x=l_{k}\left(n e^{2}[D(n)]^{-1}\right)=r_{2}(k)$, say,

$$
\begin{equation*}
f(x)=e_{k+1}(x)=\exp \left(n e^{2}[D(n)]^{-1}\right) \tag{19}
\end{equation*}
$$

By applying Lemma 1 to (18) we get for the interval $\left[0, r_{2}\right]$

$$
\begin{align*}
&|p| \leqslant \exp \left(\frac{2 n}{\left(l_{1} n\right)\left(l_{2} n\right) \ldots\left(l_{k} n\right)}\right) T_{n}\left(\frac{2 l_{k}\left(n e^{2}[D(n)]^{-1}\right)}{l_{k}\left(n[D(n)]^{-1}\right)}-1\right)  \tag{20}\\
& \quad \times \exp \left(2 n[D(n)]^{-1}\right) \exp \left(4 n[D(n)]^{-1}\right) .
\end{align*}
$$

From (19) and (20), it is easy to see that

$$
\left\|\frac{1}{f(x)}-\frac{1}{p(x)}\right\|_{\left[0, r_{2}\right]} \geqslant \exp \left(-c n[D(n)]^{-1}\right)
$$

for some constant $c$, which contradicts our earlier assumption (17). Hence the required result is proved.

Theorem 3. Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0, k \geqslant 1\right)$ be any entire function of order $\rho(0<\rho<\infty)$, type $\tau$, and lower type $\omega(0<\omega \leqslant \tau<\infty)$. Then

$$
\begin{aligned}
0 & <\left(e \omega^{2} / e^{2 \omega / \tau(e+1)} \tau^{2}(e+1) 4^{\rho}\right)^{x_{1} / x_{2}} \leqslant \liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{\rho / n} \\
& \leqslant \limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{\rho / n} \leqslant \exp (-\omega /(e+1) \tau)<1
\end{aligned}
$$

where $x_{1}$ is the greatest and $x_{2}$ the smallest root of equation (5).
Proof. If $f(z)$ is an entire function of order $\rho(0<\rho<\infty)$ and type $\tau$ $(0<\tau<\infty)$, then, for each $\varepsilon>0$, there is an $n_{2}=n_{2}(\varepsilon)$ such that, for all $n \geqslant n_{2}(\varepsilon)$, we have ([2], p. 11)

$$
\begin{equation*}
\left|a_{n}\right| \leqslant(\rho e \tau(1+\varepsilon) / n)^{n / \rho} \tag{21}
\end{equation*}
$$

As earlier, we have

$$
\begin{align*}
0 & \leqslant \frac{1}{S_{n_{2}}(x)}-\frac{1}{f(x)} \leqslant a_{0}^{-2}\left(f(x)-S_{n_{2}}(x)\right) \leqslant a_{0}^{-2} \sum_{k=n_{4}+1}^{\infty} a_{k} x^{k}  \tag{22}\\
& \leqslant a_{0}^{-2} \sum_{k=n_{3}+1}^{\infty} a_{k} y^{k} \quad(0 \leqslant x \leqslant r) .
\end{align*}
$$

On the other hand, for each $r>0$, we can find ([2], p. 12) an $n_{3}=n_{3}(r)$ such that for all $n \geqslant n_{3} \dagger$ and $x \geqslant r$,

$$
\begin{equation*}
0 \leqslant \frac{1}{S_{n_{3}}(x)}-\frac{1}{f(x)} \leqslant \frac{1}{S_{n_{3}}(x)} \leqslant \frac{1}{m(r)} . \tag{23}
\end{equation*}
$$

Now two possibilities occur in (23): (i) $n_{3}>n_{2}$, or (ii) $n_{3} \leqslant n_{2}$. If (i) is true, then in (22) we replace $S_{n_{2}}(x)$ by $S_{n_{s}}(x)$, that is,

$$
0 \leqslant \frac{1}{S_{n_{8}}(x)}-\frac{1}{f(x)} \leqslant a_{0}^{-2} \sum_{k=n+1}^{\infty} a_{k} r^{k} .
$$

If (ii) is true, then in (23) we replace $S_{n_{\mathrm{a}}}(x)$ by $S_{n_{2}}(x)$, that is, for all $x \geqslant r$,

$$
0 \leqslant \frac{1}{S_{n_{2}}(x)}-\frac{1}{f(x)} \leqslant \frac{1}{m(r)},
$$

where

$$
\begin{equation*}
r=(n / \rho \tau(e+1)(1+\varepsilon))^{1 / \rho} . \tag{24}
\end{equation*}
$$

In either case we choose $n=\max \left(n_{2}, n_{3}\right) . \ddagger$ A simple calculation based on (21) and (22') gives us, for $0 \leqslant x \leqslant r$,

$$
\begin{align*}
0 \leqslant \frac{1}{S_{n}(x)}-\frac{1}{f(x)} & \leqslant a_{0}^{-2} \sum_{k=n+1}^{\infty} a_{k} r^{k}  \tag{25}\\
& \leqslant a_{0}^{-2} \sum_{k=n+1}^{\infty}\left(\frac{p e \tau(1+\varepsilon)}{\rho \tau(e+1)(1+\varepsilon)}\right)^{k / \rho} \\
& \leqslant a_{0}^{-2} \sum_{k=n+1}^{\infty}\left(\frac{e}{e+1}\right)^{k / \rho} \\
& \leqslant a_{0}^{-2}\left(\frac{e}{e+1}\right)^{(n+1) / \rho}\left(\frac{(e+1)^{1 / \rho}}{(e+1)^{1 / p}-e^{1 / \rho}}\right) .
\end{align*}
$$

On the other hand, from ( $2^{\prime}$ ) and (23'), for all $r \geqslant r_{3}(\varepsilon)$,

$$
\begin{equation*}
m(r) \geqslant \exp [r \rho \omega(1-\varepsilon)]=\exp \left(\frac{\omega n(1-\varepsilon)}{(\varepsilon+1) \rho \tau(1+\varepsilon)}\right)=G\left(\frac{n(1-\varepsilon)}{(1+\varepsilon)}, \rho, \omega, \tau\right), \tag{26}
\end{equation*}
$$

## $\dagger n_{3}$ denotes the rank of the maximum term.

$\ddagger$ It is easy to verify that $n_{a}(r) \leqslant n(r)$ for the value of $r$ given in (24).
where $\varepsilon$ is arbitrary. We easily obtain from (25) and (26) that

$$
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n} \leqslant \exp (-\omega / \rho \tau(e+1))<1 .
$$

Now we shall prove the other inequality of Theorem 3 . As the coefficients of $f(x)$ are non-negative, we have from (2), for all large $r \geqslant r_{4}(\varepsilon)$,
(27) $0 \leqslant f(x) \leqslant f(r)=M(r) \leqslant \exp \left(r^{\rho} \tau(1+\varepsilon)\right) \quad\left(0 \leqslant x \leqslant r, r \geqslant r_{4}(\varepsilon)\right)$.

Now from (27) we have, for
that

$$
r=\left\{\omega n(1+2 \varepsilon)^{-1} \rho^{-1} \tau^{-2}(e+1)^{-1}\right\}^{1 / \rho}=H(n, \rho, \omega, \tau),
$$

$$
\begin{aligned}
0 \leqslant f(x) & \leqslant f\left[\left(\frac{\omega n}{\tau^{2} \rho(e+1)(1+2 \varepsilon)}\right)^{1 / \rho}\right] \\
& \leqslant \exp \left(\frac{n \omega(1+\varepsilon)}{(1+2 \varepsilon) \tau \rho(e+1)}\right) \\
& <G(n, \rho, \omega, \tau)=\exp \left(\frac{n \omega}{\tau(e+1) \rho}\right) \leqslant \frac{1}{\lambda_{0, n}}
\end{aligned}
$$

for all $n \geqslant n_{4}$. Next, we take the rational function $r_{0, n}^{*}=1 / p_{n}^{*}\left(r_{0, n}^{*} \in \pi_{0, n}\right)$ which gives the best approximation in the sense of (1); that is, for all $n \geqslant n_{5}$,

$$
\begin{equation*}
\lambda_{0, n} \equiv\left\|\frac{1}{f(x)}-\frac{1}{p^{*}(x)}\right\|_{\|(0, \infty)} . \tag{28}
\end{equation*}
$$

A simple manipulation based on (28) gives us

$$
\begin{align*}
-f^{2}(x) /\left(f(x)+\frac{1}{\lambda_{0, n}}\right) & \leqslant p_{n}^{*}-f(x)  \tag{29}\\
& \leqslant f^{2}(x) /\left(\frac{1}{\lambda_{0, n}}-f(x)\right) \quad(0 \leqslant x \leqslant H(n, \rho, \omega, \tau))
\end{align*}
$$

Clearly the right-hand side of inequality (29) is monotonic increasing with $x$. Hence we write

$$
\begin{equation*}
\left\|p_{n}^{*}-f(x)\right\| \leqslant G(2 n, \rho, \omega, \tau) /\left(\frac{1}{\lambda_{0, n}}-G(n, \rho, \omega, \tau)\right) \tag{30}
\end{equation*}
$$

$$
(0 \leqslant x \leqslant H(n, \rho, \omega, \tau)) .
$$

Next, let

$$
\begin{equation*}
E_{n}(f) \equiv \inf _{p_{n} \in \pi_{n}}\left\|p_{n}(x)-f(x)\right\|_{(0, H(n, p, 0, v))^{\prime}} \tag{31}
\end{equation*}
$$

From (30) and (31) we get, for all $n \geqslant n_{6}$,

$$
\begin{equation*}
E_{n}(f) \leqslant G(2 n, \rho, \omega, \tau) /\left(\frac{1}{\lambda_{0, n}}-G(n, \rho, \omega, \tau)\right) . \tag{32}
\end{equation*}
$$

To obtain a lower bound for $E_{n}$ we use a result of Bernstein ([1], p. 10) which gives us, in the interval $[0, H(n, \rho, \omega, \tau)]$,

$$
\begin{equation*}
E_{n} \geqslant\left(\frac{n \omega}{\tau^{2}(e+1) \rho(1+2 \varepsilon)}\right)^{(n+1) / \rho} \frac{a_{n+1}}{2^{2 n+1}+} \tag{33}
\end{equation*}
$$

From (32) and (33) we get

$$
\begin{equation*}
\frac{a_{n+1}[H(n, \rho, \omega, \tau)]^{n+1}}{2^{2 n+1}} \leqslant G(2 n, \rho, \omega, \tau) /\left(\frac{1}{\lambda_{0, n}}-G(n, \rho, \omega, \tau)\right) \tag{34}
\end{equation*}
$$

for all $n \geqslant n_{7}$.
From (3) we have, for a sequence of values of $n=n_{p}+1$ satisfying the assumption (4),

$$
\begin{equation*}
a_{n_{p}+1} \geqslant\left(\rho e \omega(1-\varepsilon) /\left(n_{p}+1\right)\right)^{\left(n_{p}+1\right) / \rho} . \tag{35}
\end{equation*}
$$

From (34) and (35) we get

$$
\begin{align*}
\left(\frac{\rho \rho \omega(1-\varepsilon)}{n_{p}+1}\right)^{\left(n_{p}+1\right) / \rho} \frac{\left[H\left(n_{p}, \rho, \omega, \tau\right)\right]^{n_{p}+1}}{2^{2 n_{p}+1}} &  \tag{36}\\
& \leqslant G(2 n, \rho, \omega, \tau) /\left(\frac{1}{\lambda_{0, n}}-G(n, \rho, \omega, \tau)\right) .
\end{align*}
$$

It is easy to obtain from (36) that

$$
\begin{align*}
\frac{1}{\lambda_{0, n_{p}}} & \leqslant G\left(n_{p}, \rho, \omega, \tau\right)+\frac{G\left(2 n_{p}, \rho, \omega, \tau\right)\left(n_{p}+1\right)^{\left(n_{p}+1\right) / \rho 2^{2 n_{p}+1}}}{\left[\{\rho e \omega(1-\varepsilon)\}^{1 / \rho} H\left(n_{p}, \rho, \omega, \tau\right)\right]^{n_{p}+1}}  \tag{37}\\
& \leqslant 2\left[\exp \left(\frac{2 n_{p} \omega}{\tau(e+1) \rho}\right)\right]\left(\frac{4 \rho \tau^{2} \rho(e+1)(1+2 \varepsilon)}{\omega^{2}(1-\varepsilon) e}\right)^{\left(n_{p}+1\right) / \rho}\left(\frac{n_{p}+1}{n_{p}}\right)^{\left(n_{p}+1\right) / \rho}
\end{align*}
$$

Now by adopting the technique used on p. 373 of [19] we can easily obtain from (37) and (4) the fact that

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\liminf }\left(\lambda_{0, n}\right)^{\rho / n} \geqslant\left(\frac{e \omega^{2}}{e^{2 \omega / \tau}(e+1)} \tau^{2}(e+1) 4^{\rho}\right)^{x_{1} / x_{n}} \tag{38}
\end{equation*}
$$

Remarks. (1) Under the assumptions of Theorem 3, Reddy ([16]) has recently obtained the following sharper result

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n} \geqslant\left(2^{2+1 / \rho} \tau^{1 / \rho} \omega^{-1 / \rho}-1\right)^{-2}
$$

(2) There exist entire functions which fail to satisfy the assumptions of Theorem 3, but for which we can still find two constants $c_{1}$ and $c_{2}$ $\left(0<c_{1} \leqslant c_{2}<1\right)$ such that

$$
0<c_{1} \leqslant \liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n} \leqslant \limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n} \leqslant c_{2}<1 .
$$

Example 1. Let

$$
f(x)=1+\sum_{k=2}^{\infty}\left(\frac{\log n}{n}\right)^{n} x^{n} .
$$

This is an entire function of order $\rho=1$ and type $\tau=\infty$. For this function the maximum module $M(r)$ is given by

$$
\begin{equation*}
f(r)=M(r) \sim \exp \left(\frac{r}{e} \log \frac{r}{e}\right) . \tag{39}
\end{equation*}
$$

This function clearly satisfies the growth condition (3.1) of [8]; hence there exists a constant $q>1$ for which

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\limsup }\left(\lambda_{0, n}\right)^{1 / n}=\frac{1}{q}<1 . \tag{40}
\end{equation*}
$$

From (4) it is easy to see that, for all large $n \geqslant n_{8}(\varepsilon)$,

$$
\begin{equation*}
q_{1}^{n}=[q(1-\varepsilon)]^{n} \leqslant 1 / \lambda_{0, n^{*}} \tag{41}
\end{equation*}
$$

From (39) we have

$$
0 \leqslant f(x) \leqslant f(r)<\exp (r \log (r / e)) .
$$

Let

$$
\begin{equation*}
r \log (r / e)=\frac{1}{2} n \log q_{1} \tag{42}
\end{equation*}
$$

That is,

$$
r \sim \frac{n \log q_{1}}{2 \log \left(\frac{1}{2} n \log q_{1}\right)} .
$$

From (41) and (42) we get, for all $n \geqslant n_{9}$,

$$
0 \leqslant f(x) \leqslant f(r) \leqslant \exp (r \log (r / e)) \leqslant q_{1}^{n / 2}<1 / \lambda_{0, n}
$$

Now proceeding exactly as in the proof of the second part of Theorem 3 we get, for the value of $r$ given in (42) and for all $n \geqslant n_{10}$,

$$
\begin{equation*}
\left(\frac{n}{\log \left(\frac{1}{2} n \log q_{1}\right)}\right)^{n+1} \frac{a_{n+1}}{2^{2 n+1}} \leqslant q_{1}^{n} /\left(\frac{1}{\lambda_{0, n}}-q_{1}^{n / 2}\right) . \tag{43}
\end{equation*}
$$

From (43) it is easy to see that

$$
\begin{aligned}
\frac{1}{\lambda_{0, n}} & \leqslant \frac{2^{2 n+1} q_{1}{ }^{n}\left[\log \left(\frac{1}{2} n \log q_{1}\right)\right]^{n+1}}{n^{n+1} a_{n+1}}+q_{1}^{n / 2} \\
& \leqslant 2^{2 n+1} q_{1}{ }^{n}\left(\frac{\log \left(\frac{1}{2} n \log q_{1}\right)}{n \log (n+1)}\right)^{n+1}(n+1)^{n+1}+q_{1}^{n / 2}
\end{aligned}
$$

In other words,

$$
\begin{equation*}
\frac{1}{\lambda_{0, n}} \leqslant 2^{2 n+2} q_{1}{ }^{n}\left(\frac{n+1}{n}\right)^{n+1}\left(\frac{\log \left(\frac{1}{2} n\right)+\log \log q_{1}}{\log (n+1)}\right)^{n+1} . \tag{44}
\end{equation*}
$$

A simple manipulation based on (44) gives us, if we take $q_{1}$ to be very close to $q$,

$$
\underset{n \rightarrow \infty}{\liminf }\left(\lambda_{0, n}\right)^{1 / n} \geqslant 1 / 4 q .
$$

Example 2. Let

$$
f(x)=1+\sum_{n=2}^{\infty}\left(\frac{x}{n \log n}\right)^{n} .
$$

This is an entire function of order $\rho=1$ and type $\tau=0$. For this function

$$
\begin{equation*}
f(r) \sim \exp \left(\frac{r}{e \log (r / e)}\right) \tag{45}
\end{equation*}
$$

$f(r)$ satisfies the growth condition (3.1) given in [8]; hence there exists a $q>1$ such that

$$
\begin{equation*}
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n}=\frac{1}{q}<1 . \tag{46}
\end{equation*}
$$

As before from (46) we can find, for all $n \geqslant n_{11}(\varepsilon)$, a $q_{1}<q$ such that

$$
\begin{equation*}
\lambda_{0, n} \leqslant q_{1}^{-n} . \tag{47}
\end{equation*}
$$

Let

$$
\begin{equation*}
\frac{r}{2 \log (r / e)}=\frac{1}{2} n \log q_{1^{*}} \tag{48}
\end{equation*}
$$

Then for some $c>0, r \sim n \log \left(c n \log q_{1}\right)$. From (45), (47), and (48) we obtain, for all $n \geqslant n_{12}$,

$$
0 \leqslant f(x) \leqslant f(r) \leqslant \exp \left(\frac{(1+\varepsilon) r}{e \log (r / e)}\right) \leqslant q_{1}^{n / 2}<\frac{1}{\lambda_{0, n}}
$$

and

$$
\begin{equation*}
\frac{n^{(n+1)}\left[\log \left(c n \log q_{1}\right)\right]^{n+1} a_{n+1}}{2^{2 n+1}} \leqslant q_{1}^{n} /\left(\frac{1}{\lambda_{0, n}}-q_{1}^{n / 2}\right) . \tag{49}
\end{equation*}
$$

From (49) we get as before, for $a_{n}=(n \log n)^{-n}$,

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n} \geqslant 1 / 4 q .
$$

Theorem 4. Let $f(z)=1+\sum_{k-1}^{\infty} a_{k} z^{k}, a_{k}=\left(d_{1} d_{2} \ldots d_{k}\right)^{-1}$ with $d_{k+1}>d_{k}>0$ $(k \geqslant 1)$, be an entire function of finite order $\rho$. Then for any $\varepsilon>0$ and all large $n \geqslant n_{13}(\varepsilon)$, we have

$$
\begin{equation*}
\frac{d_{1} d_{2} d_{3} \ldots d_{n}}{2^{4 n} d_{n}^{2(\rho+e)} d_{n+1} d_{n+2} \cdots d_{2 n}} \leqslant \lambda_{0,2 n-1} \leqslant \frac{d_{1} d_{2} d_{3} \ldots d_{n} d_{2 n+1}}{d_{n+1} d_{n+2} \cdots d_{2 n}\left(d_{2 n+1}-d_{2 n}\right)} . \tag{50}
\end{equation*}
$$

Proof. The second half of (50) follows from the proof of Theorem 5 of [4]. 5388.3.31

To prove the first half of (50) observe that, for $0 \leqslant x \leqslant r=d_{n}$, Lemmas 2 and 3 hold and that, for all $n \geqslant \hat{n}(\varepsilon)$,

$$
\begin{align*}
0 & \leqslant f(x) \leqslant M(r) \leqslant m(r) r^{\rho+n}  \tag{5l}\\
& =m\left(d_{n}\right) d_{n}^{\rho+\varepsilon} \\
& =\frac{d_{n}{ }^{n} d_{n}^{\rho+\varepsilon}}{d_{1} d_{2} \ldots d_{n}}<\frac{d_{n+1} d_{n+2} \ldots d_{2 n}\left(d_{2 n+1}-d_{2 n}\right)}{2 d_{2 n+1}}=\frac{\left(d_{2 n+1}-d_{2 n}\right)}{2 J\left(d_{n}\right) d_{2 n+1}} .
\end{align*}
$$

This follows because when $x=d_{n}$ we know from Lemma 3 that the $n$th term becomes the maximum term, that is,

$$
m\left(d_{n}\right)=d_{n}^{n} / d_{1} d_{2} \ldots d_{n} .
$$

As before we choose $p^{*}(x) \in \pi_{2 n-1}$ such that $p^{*}(x)$ gives the best approximation to $f(x)$ in the sense of (1), that is,

$$
\begin{equation*}
\lambda_{0,2 n-1} \geqslant\left\|\frac{1}{f(x)}-\frac{1}{p^{*}(x)}\right\|_{(0, \infty)} \quad\left(p^{*} \in \pi_{2 n-1}\right) . \tag{52}
\end{equation*}
$$

A simple calculation based on (52) gives us (as in the proof of Theorem 3)

$$
\begin{equation*}
\left\|f-p_{2 n-1}^{*}\right\|<\{f(x)\}^{2} /\left(\frac{1}{\lambda_{0,2 n-1}}-f(x)\right) \quad\left(0 \leqslant x \leqslant r=d_{n}\right) . \tag{53}
\end{equation*}
$$

From (51) and (53) we obtain

$$
\begin{align*}
& \left\|f-p_{2 n-1}^{*}\right\|  \tag{54}\\
& \quad \leqslant d_{n}^{2 n} d_{n}^{2(\rho+\sigma)} /\left(d_{1} d_{2} \ldots d_{n}\right)^{2}\left(\frac{1}{\lambda_{0,2 n-1}}-\frac{d_{n}{ }^{n} d_{n}{ }^{\rho+e}}{d_{1} d_{2} \ldots d_{n}}\right) \quad\left(0 \leqslant x \leqslant d_{n}\right) .
\end{align*}
$$

Let

$$
\begin{equation*}
E_{2 n-1}(f)=\min _{d_{2 n-1} \in r_{2 n-1}}\left\|f-g_{2 n-1}\right\|_{\left[0, d_{k}\right]} . \tag{55}
\end{equation*}
$$

From (54) and (55) we get

$$
\begin{align*}
& E_{2 n-1}(f)  \tag{56}\\
& \quad \leqslant d_{n}^{2 n} d_{n}^{2(\rho+e)} /\left(d_{1} d_{2} \ldots d_{n}\right)^{2}\left(\frac{1}{\lambda_{0,2 n-1}}-\frac{d_{n}^{n} d_{n}{ }^{\rho+\rho}}{d_{1} d_{2} \ldots d_{n}}\right) \quad\left(0 \leqslant x \leqslant d_{n}\right) .
\end{align*}
$$

To obtain a lower bound for $E_{2 n-1}(f)$ we use (as before) a result of Bernstein ( $[\mathbf{1}], \mathrm{p} .10$ ), which gives us for $x=d_{n}$,

$$
\begin{equation*}
E_{2 n-1}(f) \geqslant a_{2 n} d_{n}^{2 n} / 2^{2 n 2^{2 n-1}} \tag{57}
\end{equation*}
$$

From (56) and (57) we get, for all $n \geqslant n_{14}$,

$$
\begin{equation*}
J\left(d_{n}\right) \leqslant 2^{4 n-1} d_{n}^{2(\rho+e)} /\left(\frac{1}{\lambda_{0,2 n-1}}-\frac{d_{n}^{n} d_{n}^{p+e}}{d_{1} d_{2} \ldots d_{n}}\right) . \tag{58}
\end{equation*}
$$

From (58) it is easy to calculate that

$$
\frac{1}{\lambda_{0,2 n-1}} \leqslant \frac{2^{4 n} d_{n}^{2(\rho+e)}}{J\left(d_{n}\right)} .
$$

Therefore for all large $n$, we have

$$
\frac{d_{1} d_{2} d_{3} \ldots d_{n}}{2^{4 n} d_{n}^{2(\rho+n)} d_{n+1} d_{n+2} \ldots d_{2 n}} \leqslant \lambda_{0,2 n-1} \leqslant \frac{d_{1} d_{2} \ldots d_{n} d_{n n+1}}{d_{n+1} d_{n+2} \cdots d_{2 n}\left(d_{2 n+1}-d_{2 n}\right)} .
$$

Examples. (1) Let

$$
f(x)=1+\sum_{n=1}^{\infty} \frac{x^{n}}{2^{\log 23^{\log 3} \ldots n^{\log n}} .}
$$

For this function we get from (50)

$$
\lim _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 /(n \log n)}=\frac{1}{2} .
$$

It is interesting to note that this function fails to satisfy the assumptions of Theorem 7 of [8] and Theorem $7^{\prime}$ of [12], because $p_{t}=\Lambda+1=\infty$. But our present method which is much simpler than the methods used in [8] and [12] gives us more precise information.
(2) Let

$$
f(x)=1+\sum_{n=1}^{\infty} \frac{x^{n}}{2^{2} 3^{3} 4^{4} \ldots n^{n}} .
$$

This function also fails to satisfy the assumptions of Theorem 7 of [8] and Theorem $7^{\prime}$ of [12], because in this case $\Lambda=1$, that is, $p_{l}=2$ and $\tau_{l}=0$. For this function we get by ( 50 )

$$
\lim _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{1 / n^{2} \log n}=e^{-1 / 4}
$$

(3) Let

$$
f(x)=1+\sum_{n=1}^{\infty} \frac{x^{n}}{\delta^{2}} \quad(1<\delta<\infty) .
$$

For this function $\Lambda=0$, whence it also fails to satisfy the assumptions of Theorem 7 of [8] and Theorem $7^{\prime}$ of [12]; but we obtain by (50)

$$
\lim _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{2-n-1}=1 / \delta
$$

Theorem 5. Let $f(x)=1+\sum_{k=1}^{\infty}\left(d_{1} d_{2} \ldots d_{k}\right)^{-1} x^{k}\left(d_{k+1}>d_{k}>0, k \geqslant 1\right)$ be an entire function of infinite order. Then for each $\varepsilon>0$, there exist infinitely many $n$ for which

$$
\lambda_{0,2 n-1} \geqslant\left[K\left(d_{n}\right)\right]^{1+e} .
$$

Proof. As before when $x=d_{n}, d_{n} n / d_{1} d_{2} d_{3} \ldots d_{n}$ becomes the maximum term of $f$. Let $t_{n}=x^{n} / d_{1} d_{2} \ldots d_{n}$. Then

$$
\begin{align*}
f(x)=t_{n} & +t_{n-1}\left(1+\frac{t_{n-2}}{t_{n-1}}+\frac{t_{n-3}}{t_{n-2}}+\ldots+t_{0}\right)  \tag{59}\\
& +t_{n+1}\left(1+\frac{t_{n+2}}{t_{n+1}}+\frac{t_{n+3}}{t_{n+1}}+\ldots\right) .
\end{align*}
$$

But

$$
\begin{aligned}
& \frac{t_{n+2}}{t_{n+1}}=\frac{x}{d_{n+2}}<\frac{d_{n+1}}{d_{n+2}}, \\
& \frac{t_{n+3}}{t_{n+1}}=\frac{x^{2}}{d_{n+2} l_{n+3}}<\left(\frac{d_{n+1}}{d_{n+2}}\right)^{2},
\end{aligned}
$$

and so on. Hence

$$
\begin{equation*}
\left|\frac{t_{n+2}}{t_{n+1}}+\frac{t_{n+2}}{t_{n+1}}+\ldots\right|<\frac{d_{n+1}}{d_{n+2}-d_{n+1}} . \tag{60}
\end{equation*}
$$

Similarly

$$
\frac{t_{n-2}}{t_{n-1}} \leqslant\left(\frac{d_{n-1}}{d_{n}}\right), \quad \frac{t_{n-3}}{t_{n-1}} \leqslant\left(\frac{d_{n-1}}{d_{n}}\right)^{2},
$$

and so on. Therefore

$$
\begin{equation*}
\left|\frac{t_{n-2}}{t_{n-1}}+\frac{t_{n-3}}{t_{n-1}}+\ldots\right|<\frac{d_{n-1}}{d_{n}-d_{n-1}} . \tag{61}
\end{equation*}
$$

From (59), (60), and (61), we obtain

$$
\begin{equation*}
f(x)=t_{n}+t_{n-1}(1+\varphi)+t_{n+1}\left(1+\varphi_{1}\right), \tag{62}
\end{equation*}
$$

where

$$
|\varphi|<\frac{d_{n-1}}{d_{n}-d_{n-1}}, \quad\left|\psi_{1}\right|<\frac{d_{n+1}}{d_{n+2}-d_{n+1}} .
$$

From (62) we get, for $x=d_{n}$,

$$
f(x) \leqslant \frac{d_{n}{ }^{n}}{d_{1} d_{2} d_{3} \ldots d_{n}}+t_{n-1}(1+\varphi)+t_{n+1}\left(1+\varphi_{1}\right)=\left[K\left(d_{n}\right)\right]^{-1 / 8} .
$$

For all sufficiently large $n$ we can find an $\varepsilon>0$ such that

$$
\begin{equation*}
f\left(d_{n}\right) \leqslant\left[K\left(d_{n}\right)\right]^{-(1+e) / 8} . \tag{63}
\end{equation*}
$$

Now let us suppose that for all large $n$ and all $x(0 \leqslant x<\infty)$

$$
\begin{equation*}
\left|\frac{1}{f(x)}-\frac{1}{p_{2 n-1}(x)}\right| \leqslant\left[K\left(d_{n}\right)\right]^{1+e} . \tag{64}
\end{equation*}
$$

From (63) and (64) we get

$$
|p|<\left[K\left(d_{n}\right)\right]^{-(1+\sigma) / 4} .
$$

Because of the assumption that $f(x)$ is of infinite order for every large $r>0$ we can find sufficiently large $n$ such that

$$
\begin{equation*}
f\left[d_{n}\left(1+r^{-1}\right)\right] \geqslant\left[f\left(d_{n}\right)\right]^{18} . \tag{65}
\end{equation*}
$$

Therefore from (62) and (65) we get

$$
\begin{equation*}
f\left[d_{n}\left(1+r^{-1}\right)\right] \geqslant\left[K\left(d_{n}\right)\right]^{-2(1+\varepsilon)} . \tag{66}
\end{equation*}
$$

On the other hand by applying Lemma 1 to $p(x)$ we get

$$
\begin{equation*}
p\left[d_{n}\left(1+r^{-1}\right)\right] \leqslant\left[K\left(d_{n}\right)\right]^{-(1+6) / 2} . \tag{67}
\end{equation*}
$$

From (66) and (67) we get

$$
\begin{align*}
{\left[K\left(d_{n}\right)\right]^{1+\varepsilon} } & \leqslant\left[K\left(d_{n}\right)\right]^{(1+\varepsilon) / 2}\left\{1-\left[K\left(d_{n}\right)\right]^{3(1+\omega) / 2}\right\}  \tag{68}\\
& \leqslant \frac{1}{p_{n}\left(d_{n}\left(1+r^{-1}\right)\right)}-\frac{1}{f\left(d_{n}\left(1+r^{-1}\right)\right)},
\end{align*}
$$

that is,

$$
\left\{K\left(d_{n}\right)\right\}^{(1+a) / 2}+\left\{K\left(d_{n}\right)\right\}^{3(1+e) / 2}<1,
$$

which gives the required result, beeause the conclusion (68) contradicts our earlier assumption (64).

Theorem 6. Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}\left(a_{0}>0, a_{k} \geqslant 0, k \geqslant 1\right)$ be any entire. function satisfying the assumption that

$$
1 \leqslant \underset{r \rightarrow \infty}{\limsup } \frac{\log \log M(r)}{\log \log r}=\Lambda+1<\infty
$$

Then for any $\varepsilon>0$,

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{n^{-1-(11 / \Lambda+\theta)}}<1
$$

Proof. We get from Theorems 1 and 3 of [11]

$$
\limsup _{n \rightarrow \infty} \frac{\log n}{\log \left\{n^{-1} \log a_{n}^{-1}\right\}}=\Lambda .
$$

From this we easily obtain that, for any $\varepsilon>0$,

$$
\lim _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n} \exp \left(n^{1 /(\Lambda+\varepsilon)}\right)=0 .
$$

As earlier, let $u_{n}=a_{n}^{-1 / n}$; and let $h=1 /(\Lambda+\varepsilon)$. Then $u_{n} \exp \left(-n^{h}\right) \rightarrow \infty$. This implies that there exist infinitely many $n$ for which

$$
\begin{equation*}
\frac{u_{n+1}}{\exp \left[(n+l)^{n}\right]} \geqslant \frac{u_{n}}{\exp \left(n^{h}\right)} \quad(l=0,1,2, \ldots) . \tag{69}
\end{equation*}
$$

Now let

$$
x \geqslant \theta^{n^{h}} u_{n} \quad\left(1<\theta<\exp \left(2^{h-1}\right)\right.
$$

Then

$$
\begin{equation*}
S_{2 n}(x) \geqslant a_{n} x^{n} \geqslant a_{n} u_{n}^{n} \theta^{n^{3+1}}=\theta^{n^{k+1}} . \tag{70}
\end{equation*}
$$

Hence, as usual we get from (70), for $x \geqslant \theta^{n^{b}} u_{n}$,

$$
\begin{equation*}
0 \leqslant \frac{1}{S_{2 n}(x)}-\frac{1}{f(x)} \leqslant \frac{1}{S_{2 n}(x)} \leqslant \frac{1}{a_{n} x^{n}} \leqslant \theta^{-n^{x+1}} \tag{71}
\end{equation*}
$$

On the other hand, let

$$
x<u_{n}(\theta)^{n^{n}}
$$

Then as before it is easy to note from (69) that, for any $k>2 n$,

$$
\left|a_{k}\right|<u_{n}^{-k} \exp \left(k\left(n^{h}-k^{h}\right)\right) .
$$

This formula implies that

$$
\begin{aligned}
\sum_{k=2 n+1}^{\infty} a_{k} x^{k} & \leqslant \sum_{k=2 n+1}^{\infty}\left\{\exp k\left(n^{h}-k^{h}\right)\right\} \theta^{n^{\pi_{k}}} \\
& \leqslant \sum_{k=2 n+1}^{\infty}\left(\frac{(\theta e)^{n^{h}}}{\exp k^{h}}\right)^{k} \\
& \leqslant\left(\frac{(\theta e)^{n^{n}}}{\exp (2 n)^{h}}\right)^{2 n+1}\left(\frac{\exp (2 n)^{h}}{\exp (2 n)^{h}-(\theta e)^{n^{\lambda}}}\right) .
\end{aligned}
$$

From this we have

$$
\begin{align*}
\lambda_{0,2 n} & \leqslant\left\|\frac{1}{f(x)}-\frac{1}{p_{2 n}(x)}\right\|  \tag{72}\\
& \leqslant a_{0}^{-2} \sum_{k=2 n+1}^{\infty} a_{h} x^{x^{k}} \\
& \leqslant\left(\frac{(\theta e)^{n^{n}}}{\exp (2 n)^{h}}\right)^{2 n+1} a_{0}-2\left(\frac{\exp (2 n)^{h}}{\exp (2 n)^{h}-(e \theta)^{n^{k}}}\right) .
\end{align*}
$$

From (71) and (72), with $\theta e<\exp \left(2^{h}\right)$, we easily obtain that

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0,2 n}\right)^{1 /\left([2 n)^{k+1}\right.}<e^{-1}(\theta \epsilon)^{1 /\left[2^{b}\right]}<1
$$

Theorem 7. Let $f(z)=a_{0}+\sum_{k=1}^{\infty} a_{n_{k}} z^{n_{k}}$, with $a_{0}>0, a_{n_{z}}>0(k \geqslant 1)$, and $\liminf \operatorname{inc\infty }_{k \rightarrow \infty}\left(n_{k+1} / n_{k}\right) \geqslant \beta>1$, be an entire function of finite order $\rho$. Then for any $\alpha(0<\alpha<1)$ and any $\varepsilon>0$, we have

$$
\liminf _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{(1-\alpha)(\rho+e) / n} \leqslant \beta^{-1}
$$

The proof of this result is very similar to the proof of the preceding theorem. Hence the details are left to the reader.

## Concluding remarks

Theorem 3 of this paper answers questions 1,2, and 4 in the affirmative. The answer to question 5 follows from Theorem 1. Question 3 is resolved in Theorem 6. The examples given at the end of Theorem 4 answer question 7. Question 6 must be answered in the negative; this follows from Theorem 4.

It may be of some interest to know whether it is possible to obtain a lower bound for

$$
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{n^{-1-u(A)}} \quad \text { (cf. Theorem II). }
$$

This has been solved in [15]. We have proved in [15], under the assumptions of Theorem II, that

$$
\limsup _{n \rightarrow \infty}\left(\lambda_{0, n}\right)^{-1-1 w \Lambda)} \geqslant \exp \left(\frac{-\Lambda}{(\Lambda+1)}\left(\frac{1}{(\Lambda+1) \tau_{l}}\right)^{1 / \Lambda}\right)
$$

It is natural to ask whether we can do much better by using the general rational functions of the form $p_{n}(x) / Q_{n}(x)$ than by using $1 / Q_{n}(x)$ in the above results. We are not able to settle this question in general (see, however, [9] and [17]). But we are able to prove the following theorem.

Theorem (cf. [14]). Let $f(z)=\sum_{k=0}^{\infty} a_{k} z^{k}\left(a_{k} \geqslant 0, k \geqslant 0\right)$ be any entire function of order $\rho(0<\rho<\infty)$, type $\tau$, and lower type $\omega(0<\omega \leqslant \tau<\infty)$. Then one cannot find algebraic polynomials $p(x)$ and $Q(x)$ with non-negative coefficients and of degree at most $n$ for which

$$
\liminf _{n \rightarrow \infty}\left\{\left\|\frac{1}{f(x)}-\frac{P(x)}{Q(x)}\right\|_{(0, \infty)}\right\}^{\text {pu/ } / n r} \leqslant(2 \sqrt{2})^{-1} .
$$

The examples 1 and 2 of Theorem 3 fail to satisfy the assumptions of the above theorem; but the conclusion of the theorem still holds for these examples, in a slightly different form.
