# A MEASURE OF THE NONMONOTONICITY OF THE EULER PHI FUNCTION 

Harold G. Diamond and Paul Erdös

1. Introduction. Let $f$ be a real valued arithmetic function satisfying $\lim _{n \rightarrow \infty} f(n)=+\infty$. Define another arithmetic function $F=F_{f}$ by setting

$$
F_{f}(n)=\#\{j<n: f(j) \geqq f(n)\}+\#\{j>n: f(j) \leqq f(n)\} .
$$

The size of the values assumed by the function $F$ provides a measure of the nonmonotonicity of $f$. In particular, $F$ is identically zero if and only if $f$ is strictly increasing.

Here we shall take $f$ to be $\varphi$, Euler's function, and study the associated function $F_{\varphi}$, which we henceforth call $F$.

We shall show that $F(n) / n$ is asymptotically representable as a function of $\varphi(n) / n$. Then we shall prove that $F(n) / n$ has a distribution function. We shall study $\max _{n \leq x} F(n)$ and $\min _{n>x} F(n)$ and investigate conditions on $\varphi(n) / n$ which lead to large and small values of $F(n) / n$.

We express our thanks to Professor Carl Pomerance for a number of helpful comments and suggestions, and to Dr. Charles R. Wall for his unpublished data on the density function of Euler's function.
2. An asymptotic formula for $F$. For $0 \leqq a, b \leqq \infty$, let

$$
\Phi(a, b)=\#\{n \leqq a: \varphi(n) \leqq b\} .
$$

We have

$$
\begin{aligned}
& \#\{j<n: \varphi(j) \geqq \varphi(n)\}=n-\Phi(n, \varphi(n))+\#\{j<n: \varphi(j)=\varphi(n)\}, \\
& \#\{j>n: \varphi(j) \leqq \varphi(n)\}=\Phi(\infty, \varphi(n))-\Phi(n, \varphi(n)) .
\end{aligned}
$$

Thus

$$
F(n)=n+\Phi(\infty, \varphi(n))-2 \Phi(n, \varphi(n))+\#\{j<n: \varphi(j)=\varphi(n)\} .
$$

It is known that

$$
\Phi(\infty, y)=\zeta y+O\left(y e^{-\sqrt{\log y}}\right),
$$

where $\zeta$ denotes the constant $\zeta(2) \zeta(3) / \zeta(6) \approx 1.9436$ [1]; and

$$
\Phi(x, y)=x g(y / x)+O\left(y e^{-\sqrt{\log y}}\right),
$$

where $g$ is a continuous, increasing function on $[0,1]$ which is determined by a contour integral [2].

Moreover, $g$ is strictly concave, as we now indicate. We have from [2, Eq. (12)] that

$$
\begin{equation*}
\alpha g^{\prime}(\alpha)=g(\alpha)-D_{\varphi}(\alpha), \quad 0<\alpha \leqq 1 . \tag{0}
\end{equation*}
$$

Here

$$
D_{\varphi}(\alpha)=\lim _{z \rightarrow \infty} \frac{1}{x} \#\{n \leqq x: \varphi(n) \leqq \alpha n\} .
$$

It is known that this limit exists and defines a continuous function of $\alpha$ (cf. [6, Ch 4], [7, §5]). Clearly $D_{\varphi}$ is nondecreasing. In fact, it is known to be strictly increasing on ( 0,1 ) [8, pp. 319, 323].

If we integrate the differential equation for $g$ and use the fact that $g(1)=1$, we obtain

$$
g(\alpha)=\alpha+\alpha \int_{\alpha}^{1} t^{-2} D_{\varphi}(t) d t
$$

and differentiating again, and differencing, we get for $0<u<v \leqq 1$

$$
\begin{aligned}
g^{\prime}(v)-g^{\prime}(u) & =-\frac{1}{v} D_{\varphi}(v)+\frac{1}{u} D_{\varphi}(u)-\int_{u}^{v} t^{-2} D_{\varphi}(t) d t \\
& =-\int_{u}^{v} t^{-1} d D_{\varphi}(t)<\left\{D_{\varphi}(u)-D_{\varphi}(v)\right\} / v<0 .
\end{aligned}
$$

Thus $g$ is strictly concave on $(0,1)$.
Noting that

$$
\begin{aligned}
\#\{j<n: \varphi(j)=\varphi(n)\} & \leqq \Phi(\infty, \varphi(n))-\Phi(\infty, \varphi(n)-1) \\
& =O\left\{\varphi(n) e^{-\sqrt{10 g} \varphi(n)}\right\},
\end{aligned}
$$

we have

$$
\frac{F(n)}{n}=1+\zeta \frac{\varphi(n)}{n}-2 g\left(\frac{\varphi(n)}{n}\right)+O\left\{\frac{\varphi(n)}{n} e^{-\sqrt{\log \varphi(n)}}\right\} .
$$

If we set

$$
\begin{equation*}
h(u)=1+\zeta u-2 g(u) \tag{1}
\end{equation*}
$$

and enlarge the error we obtain the asymptotic formula

$$
\begin{equation*}
\frac{F(n)}{n}=h(\varphi(n) / n)+O\left(e^{-\sqrt{\log n}}\right) . \tag{2}
\end{equation*}
$$

Below is an approximate graph of $h$. Note that $h$ is strictly convex.

Figure 1

## 3. A distribution function.

Theorem 1. $F(n) / n$ has a continuous distribution function.
Proof. Let $h_{0}$ denote the minimal value of $h$ and $u_{0}$ the point at which the minimum is achieved. Let $h^{*}$ denote the branch of the inverse function of $h$ which maps $\left[h_{0}, 1\right]$ onto $\left[0, u_{0}\right]$, and let $h^{* *}$ denote the branch which maps $\left[h_{0}, \zeta-1\right]$ onto $\left[u_{0}, 1\right]$. Also, let $h^{* *}(\alpha)=1$ for $\zeta-1<\alpha \leqq 1$. Note that $h^{*}$ and $h^{* *}$ are well defined, even at $u_{0}$, on account of the strict convexity of $h$.

Since $D_{\varphi}$ and $h$ are continuous, for $h_{0} \leqq \alpha \leqq 1$ we have

$$
\begin{aligned}
D_{\varphi}\left(h^{* *}(\alpha)\right)-D_{\varphi}\left(h^{*}(\alpha)\right) & =\lim _{z \rightarrow \infty} \frac{1}{x} \#\left\{n \leqq x: h^{*}(\alpha) \leqq \varphi(n) / n \leqq h^{* *}(\alpha)\right\} \\
& =\lim _{x \rightarrow \infty} \frac{1}{x} \#\{n \leqq x: h(\varphi(n) / n) \leqq \alpha\},
\end{aligned}
$$

a continuous function of $\alpha$ which vanishes at $\alpha=h_{0}$ and equals 1 for $\alpha=1$.

Given $\varepsilon>0$ we have

$$
\begin{aligned}
\lim _{x \rightarrow \infty} & \frac{1}{x} \#\left\{n \leqq x: h\left(\frac{\varphi(n)}{n}\right) \leqq \alpha-\varepsilon\right\} \leqq \lim _{x \rightarrow \infty} \frac{1}{x} \#\left\{n \leqq x: \frac{F(n)}{n} \leqq \alpha\right\} \\
& \leqq \varlimsup_{x \rightarrow \infty} \frac{1}{x} \#\left\{n \leqq x: \frac{F(n)}{n} \leqq \alpha\right\} \leqq \lim _{x \rightarrow \infty} \frac{1}{x} \#\left\{n \leqq x: h\left(\frac{\varphi(n)}{n}\right) \leqq \alpha+\varepsilon\right\} .
\end{aligned}
$$

It follows that if $h_{0} \leqq \alpha \leqq 1$, then

$$
D_{F}(\alpha)=\lim _{x \rightarrow \infty} \frac{1}{x} \#\left\{n \leqq x: \frac{F(n)}{n} \leqq \alpha\right\}=D_{\varphi}\left(h^{* *}(\alpha)\right)-D_{\varphi}\left(h^{*}(\alpha)\right) .
$$

Further, $D_{F}(\alpha)=0$ for $\alpha<h_{0}$ and $D_{F}(\alpha)=1$ for $\alpha>1$. Thus $F(n) / n$ has a continuous distribution function.
4. Upper estimates. We shall exploit the observation, based on the graph of $h$, that $F(n) / n$ is near its largest when $\varphi(n) / n$ is near 0 .

Lemma 1. For all large $x$ there exists an integer $n_{0}=n_{0}(x)$ such that $x-x \log ^{-1} x<n_{0} \leqq x$ and

$$
\begin{equation*}
\varphi\left(n_{0}\right) / n_{0} \sim e^{-\zeta} / \log \log x \sim \min _{1 \leqq m \leq x} \varphi(m) / m \tag{3}
\end{equation*}
$$

Proof. Let $p_{r}$ denote the $r$ th prime (in the usual order) and $P(r)$ the product of the first $r$ primes. Choose $r^{\prime}=r^{\prime}(x)$ to be the largest integer for which $P\left(r^{\prime}\right) \leqq x / \log x$. The prime number theorem implies that

$$
\sum_{p \leq p_{r^{\prime}}} \log p \sim p_{r^{\prime}},
$$

and hence, by an easy calculation, $p_{r^{\prime}} \sim \log x$.
Set $n_{0}=\left[x / P\left(r^{\prime}\right)\right] P\left(r^{\prime}\right)$. Then $x-P\left(r^{\prime}\right)<n_{0} \leqq x$ and

$$
\frac{\varphi\left(n_{0}\right)}{n_{0}} \leqq \prod_{p \leq p_{r^{\prime}}}\left(1-\frac{1}{p}\right) \sim \frac{e^{-\gamma}}{\log p_{r^{\prime}}} \sim \frac{e^{-\gamma}}{\log \log x} .
$$

It is known (cf. [5, Th. 328]) that

$$
\min _{1 \leq m \leq x} \varphi(m) / m \sim e^{-\tau} / \log \log x
$$

Theorem 2. As $x \rightarrow \infty$,

$$
\max _{n \leq x} F(n)=x-\left(\zeta e^{-\gamma}+o(1)\right) x / \log \log x .
$$

Proof. Let $\alpha_{0}$ (presently to be specified) be a small positive number such that $h(\alpha) \leqq h\left(\alpha_{0}\right)<1$ for $\alpha_{0}<\alpha<1$. Suppose first that $\varphi(n) / n \geqq \alpha_{0}$. Then there exists an $\varepsilon>0$ such that $F(n)<(1-\varepsilon) n$ for all sufficiently large $n$ and if $x$ is large, $F(n)<(1-\varepsilon) x$ for all $n \leqq x$ and satisfying $\varphi(n) / n \geqq \alpha_{0}$.

For small positive values of $\alpha$ we use the approximation

$$
g(\alpha)=\zeta \alpha+O\{\exp (-\exp 1 /(k \alpha))\},
$$

which holds for some absolute constant $k$ [2, Lemma 4]. If we combine this estimate with (1) and (2) we obtain

$$
\begin{equation*}
\frac{F(n)}{n}=1-\zeta \frac{\varphi(n)}{n}+O\left\{\exp \left(-\exp \frac{n}{k \varphi(n)}\right)\right\}+O\left(e^{-\sqrt{\log n}}\right) . \tag{4}
\end{equation*}
$$

The function $\alpha \mapsto 1-\zeta \alpha+c \exp \{-\exp 1 /(k \alpha)\}$ is decreasing for small positive $\alpha$. Choose $\alpha_{3}$ to be positive but so small that the function
is decreasing for $0<\alpha<\alpha_{0}$ and $h\left(\alpha_{0}\right)>\zeta-1$.
Now for $\varphi(n) / n<\alpha_{0}$ we use the inequality

$$
\varphi(n) / n \geqq\left(e^{-r}+o(1)\right) / \log \log x, \quad 1 \leqq n \leqq x,
$$

to obtain the bound

$$
F(n) \leqq x\left\{1-\left(\zeta e^{-r}+o(1)\right) / \log \log x\right\}, \quad 1 \leqq n \leqq x
$$

The $o(1)$ term tends to zero as $x \rightarrow \infty$ (independently of $n$ ).
On the other hand, taking $n_{0}$ as in the lemma yields

$$
\begin{aligned}
F\left(n_{0}\right) & =n_{0}\left\{1-\left(\zeta e^{-r}+o(1)\right) / \log \log x\right\} \\
& =x\left\{1-\left(\zeta e^{-r}+o(1)\right) / \log \log x\right\} .
\end{aligned}
$$

Define a sequence $\left\{n_{k}\right\}$ of "new highs" of $F$ by the condition $F(n)<F\left(n_{k}\right)$ for all $n<n_{k}$.

We note for later use that $\varphi\left(n_{k}\right) / n_{k} \sim e^{-\gamma} / \log \log n_{k}$ as $k \rightarrow \infty$. We can see this by noting first that $\phi\left(n_{k}\right) / n_{k} \rightarrow 0$ by the first paragraph of the proof of Theorem 2. Then we write (4) with $n=n_{k}$ and Theorem 2 with $x=n_{k}$ and equate the expressions to obtain

$$
1-\frac{\zeta \varphi\left(n_{k}\right)}{n_{k}}(1+o(1))+O\left(e^{-\sqrt{\log n}}\right)=1-\frac{\zeta e^{-r}+o(1)}{\log \log n_{k}} .
$$

Theorem 2 has two immediate consequences.
Corollary 1. $F(n)<n$ for all sufficiently large $n$.
Corollary 2.

$$
n_{k+1}-n_{k}=o\left(n_{k} / \log \log n_{k}\right), k \longrightarrow \infty .
$$

Proof. For $n_{k} \leqq x<n_{k+1}$ we have

$$
\max _{n \leq x} F(n)=F\left(n_{k}\right)
$$

or

$$
x\left\{1-\frac{\zeta e^{-\gamma}+o(1)}{\log \log x}\right\}=n_{k}\left\{1-\frac{\zeta e^{-\gamma}+o(1)}{\log \log n_{k}}\right\} .
$$

Let $x \rightarrow n_{k+1^{-}}$to obtain the corollary.
Remark. The size of $n$ or $n_{k}$ plays a vital role in the two corollaries. The first corollary is false for small $n$ as the examples $F(13)=13$ and $F(73)=75$ show.

The proof of Theorem 2 implies that $\varphi\left(n_{k}\right) / n_{k} \rightarrow 0$ as $k \rightarrow \infty$.

Numerical computation shows that the $n_{k}$ 's are primes for all $n_{k} \leqq$ 500 (the limit of the calculation). The explanation of this anomaly (apart from the effect of the error term) is as follows. Let $u_{1}$ be the number in $(0,1)$ for which $h\left(u_{1}\right)=\zeta-1$ (cf. (Fig. 1)). It appears from (4) that $u_{1} \approx .03$. Simple estimates show that $\varphi(n) / n>.03$ for all $n<e^{{ }^{18}}$. Thus for $n$ of modest size, the largest values of $h(\varphi(n) / n)$ occur for $\varphi(n) / n$ near 1 .

We conclude this section by establishing a lower bound inequality for $n_{k+1}-n_{k}$.

Theorem 3. For any $\varepsilon>0$

$$
n_{k+1}-n_{k}>n_{k}^{1-\varepsilon}, \quad k \longrightarrow \infty .
$$

Proof. Given $\varepsilon>0$ and $n_{k}$, let $p^{*}=p^{*}(k)$ denote the largest prime such that $\Pi_{p \leq p} p \leqq n_{k}$. The prime number theorem and simple estimates imply that $p^{*} \sim \log n_{k}$. We shall show that at most $\varepsilon p^{*} / \log p^{*}$ primes $p \leqq p^{*}$ fail to divide $n_{k}$. Similar estimates apply for $n_{k+1}$ and thus $n_{k}$ and $n_{k+1}$ have at least $\pi\left(p^{*}\right)-2\left[\varepsilon p^{*} / \log p^{*}\right]$ prime factors in common.

Let $w$ be an integer such that

$$
\pi(w)=\pi\left(p^{*}\right)-2\left[\varepsilon p^{*} / \log p^{*}\right] .
$$

Then we have

$$
n_{k+1}-n_{k} \geqq \prod_{p \leq w} p=\prod_{p \leq p *} p \prod_{w<p \leq p^{*}} p^{-1}
$$

Also,

$$
\sum_{w<p \leq p^{*}} \log p \leqq\left(\log p^{*}\right)\left[\pi\left(p^{*}\right)-\pi(w)\right] \leqq 2 \varepsilon p^{*},
$$

and so

$$
n_{k+1}-n_{k} \geqq \frac{n_{k}}{2 p^{*}} \exp \left[-2 \varepsilon p^{*}\right] \geqq n_{k}^{1-3 \varepsilon} .
$$

We introduce the integer

$$
N=\left[n_{k} \prod_{p<p^{*}} p^{-1}\right] \prod_{p<p p^{*}} p .
$$

Since $N \leqq n_{k}$ we have $F(N) \leqq F\left(n_{k}\right)$. We can estimate $F(N)$ and $F\left(n_{k}\right)$ because of the special form of $N$ and $n_{k}$. Also, $N$ is not much smaller than $n_{k}$. These facts will enable us to show that

$$
\#\left\{p \leqq p^{*}: p \nmid n_{k}\right\} \leqq \varepsilon p^{*} / \log p^{*} .
$$

Let $\nu$ denote the number of primes $p \leqq p^{*}$ such that $p \nmid n_{k}$. We suppose that $\nu>\varepsilon p^{*} / \log p^{*}$ and shall deduce a contradiction.

At most $\nu+1$ prime divisors of $n_{k}$ (counting multiplicity) can exceed $p^{*}$, as we now indicate. Suppose that there were at least $\nu+2$ prime divisors of $n_{k}$ exceeding $p^{*}$. For each of the $\nu$ primes $p_{i} \leqq p^{*}$ with $p_{i} \nmid n_{k}$ associate a prime $p_{i}^{\prime}>p^{*}$ with $p_{i}^{\prime} \mid n_{k}$. Each of the $p^{\prime \prime}$ s can be used at most as many times as it occurs in the factorization of $n_{k}$. We have

$$
n_{k}>n^{\prime}=n_{k} \prod_{i=1}^{\nu} p_{i} / p_{i}^{\prime} ;
$$

further $n^{\prime}$ is divisible by each prime not exceeding $p^{*}$ and by at least two primes exceeding $p^{*}$. Thus $n_{k}>n^{\prime}>p^{* 2} \Pi_{p \leq p^{*}} p$. On the other hand the definition of $p^{*}$ implies that $n_{k}<2 p^{*} \Pi_{p \leq p} . p$, contradicting the last inequality.

Let $y$ and $z$ denote composite numbers such that $\pi\left(p^{*}\right)-\pi(y)=\nu$, $\pi(z)-\pi\left(p^{*}\right)=\nu+1$. Then

$$
\begin{aligned}
\frac{\varphi\left(n_{k}\right)}{n_{k}} & =\prod_{p \leqq p^{*}}\left(1-\frac{1}{p}\right) \prod_{\substack{p>\sum_{p}^{*} \\
p \not n_{k}}}\left(1-\frac{1}{p}\right)^{-1} \prod_{\substack{p>p^{*} \\
p>n_{k}}}\left(1-\frac{1}{p}\right) \\
& \geqq \prod_{p \leqq p^{*}}\left(1-\frac{1}{p}\right)_{y<p \leqslant p^{*}} \prod_{p}\left(1-\frac{1}{p}\right)^{-1} \prod_{p<p<z}\left(1-\frac{1}{p}\right) .
\end{aligned}
$$

Letting $\nu=\eta p^{*} / \log p^{*}, \varepsilon<\eta \leqq 1$, we have

$$
\pi(y)=\pi\left(p^{*}\right)-\nu=(1-\eta+o(1)) p^{*} / \log p^{*},
$$

and so $y=(1-\eta+o(1)) p^{*}$. Similarly $z=(1+\eta+o(1)) p^{*}$. Thus

$$
\prod_{y<p \leq p^{*}}\left(1-\frac{1}{p}\right)^{-1} \prod_{p^{*}<p<z}\left(1-\frac{1}{p}\right)=\frac{\left(\log p^{*}\right)^{2}}{(\log y)(\log z)}\left(1+O\left(e^{\left.-\sqrt{\log p^{*}}\right)}\right) .\right.
$$

Differentiation shows that, for fixed $q$, the function

$$
\eta \longmapsto \frac{\log ^{2} q}{\log ((1-\eta) q) \log ((1+\eta) q)}
$$

is increasing for $0<\eta<1$. Thus

$$
\begin{aligned}
\frac{\left(\log p^{*}\right)^{2}}{(\log y)(\log z)} & \geqq \frac{\left(\log p^{*}\right)^{2}}{\log \left((1-\varepsilon) p^{*}\right) \log \left((1+\varepsilon) p^{*}\right)} \\
& \geqq\left\{1-\frac{\varepsilon+\varepsilon^{2} / 2+O\left(\varepsilon^{3}\right)}{\log p^{*}}\right\}^{-1}\left\{1+\frac{\varepsilon-\varepsilon^{2} / 2+O\left(\varepsilon^{3}\right)}{\log p^{*}}\right\}^{-1} \\
& \geqq 1+\frac{\varepsilon^{2}}{\log p^{*}}+O\left(\frac{\varepsilon^{3}}{\log p^{*}}+\frac{\varepsilon^{2}}{\log ^{2} p^{*}}\right) .
\end{aligned}
$$

Thus

$$
\prod_{y<p \leq p .}\left(1-\frac{1}{p}\right)^{-1} \prod_{p \cdot<p<z}\left(1-\frac{1}{p}\right) \geqq 1+\frac{\varepsilon^{2}}{2 \log p^{*}},
$$

provided that $k$ is sufficiently large and $\varepsilon$ sufficiently small. It follows that

$$
\frac{\varphi\left(n_{k}\right)}{n_{k}} \geqq\left(1+\frac{\varepsilon^{2}}{2 \log p^{*}}\right) \prod_{p \leq p^{*}}\left(1-\frac{1}{p}\right) .
$$

We have $\varphi(N) / N \sim e^{-r} / \log \log N$ because of the form of $N$, and $\varphi\left(n_{k}\right) / n_{k} \sim e^{-\gamma} / \log \log n_{k}$ by the argument following the proof of Theorem 2. It follows from (4), that for some $\alpha>0$,

$$
\frac{F(x)}{x}=1-\zeta \frac{\varphi(x)}{x}+O\left\{\exp \left(-\log ^{\alpha} x\right)\right\}
$$

holds for $x=N$ and $x=n_{k}$.
We combine the formulas for $F\left(n_{k}\right)$ and $F(N)$ with the bound we obtained for $\varphi\left(n_{k}\right) / n_{k}$, the inequalities

$$
n_{k} \geqq N=\left[\frac{n_{k}}{\prod_{p<p^{*}}}\right] \prod_{p<p^{*}} p>n_{k}-\prod_{p<p^{*}} p \geqq n_{k}\left(1-\frac{1}{p^{*}}\right)
$$

and $\varphi(N) / N \leqq \Pi_{p<p^{*}}\left(1-p^{-1}\right)$ to obtain

$$
\begin{aligned}
F\left(n_{k}\right) & \leqq \frac{N}{1-\frac{1}{p^{*}}}\left\{1-\zeta\left(1+\frac{\varepsilon^{2}}{2 \log p^{*}}\right) \prod_{p \leqq p^{*}}\left(1-\frac{1}{p}\right)+c e^{-\log ^{\alpha} N}\right\} \\
& <N\left\{1-\zeta \prod_{p<p^{*}}\left(1-\frac{1}{p}\right)-c \exp \left(-\log ^{\alpha} N\right)\right\} \leqq F(N),
\end{aligned}
$$

where $c$ is a positive constant. This inequality is impossible, since the $n_{k}$ 's are the new highs of $F$. It follows that at most $\varepsilon p^{*} / \log p^{*}$ primes $p \leqq p^{*}$ fail to divide $n_{k}$ and hence our lower bound for $n_{n+1}-n_{k}$ holds.
5. Small values of $F(n) / n$. We have shown in $\S 2$ that $F(n) / n \sim$ $h(\varphi(n) / n)$. The function $h$ attains a minimal value $h_{0}$ at an interior point $u_{0}$ of $(0,1)$, as we presently shall show. The point $u_{0}$ is unique by the strict convexity of $h$. Thus $F(n) / n$ is, asymptotically, near its minimal value $h_{0}$ when $\varphi(n) / n$ is near $u_{0}$.

Numerical data suggest that $u_{0}$ is near $1 / 2$ and $h_{0}$ is near $1 / 3$. We shall show that $.473<u_{0}<.475$ and $.321<h_{0}<.324$.

Lemma 2. $h^{\prime}(0)=-\zeta, h^{\prime}(1)=\zeta$.
Proof. We have by (1) that $h^{\prime}(u)=\zeta-2 g^{\prime}(u)$. The estimate (cf. [2], Lemma 4)

$$
g(u)=\zeta u+O\{\exp (-\exp 1 /(k u))\}
$$

implies that $g^{\prime}(0)=\zeta$, and hence $h^{\prime}(0)=-\zeta$. Equation (0) implies that $g^{\prime}(1)=0$, and hence $h^{\prime}(1)=\zeta$.

Thus the minimum of $h$ is achieved in the open interval $(0,1)$. We shall now establish a formula which will lead to estimates for $g(1 / 2)$. This will be useful because of the close connection between $g$ and $h$ and the proximity of $u_{0}$ to $1 / 2$.

## Lemma 3.

$$
\begin{gathered}
g(1 / 2)=\frac{1}{2}+\frac{\zeta}{6}-\left\{\left(\frac{\zeta}{4}-g\left(\frac{1}{4}\right)\right)-\left(\frac{\zeta}{8}-g\left(\frac{1}{8}\right)\right)\right. \\
\left.+\left(\frac{\zeta}{16}-g\left(\frac{1}{16}\right)\right)-\cdots\right\} .
\end{gathered}
$$

Proof. We estimate

$$
\#\{n \leqq x: n \text { odd, } \varphi(n) \leqq y\},
$$

a problem closely related to the main theorem of [2]. The generating function

$$
\begin{aligned}
F(s, z) & \stackrel{\text { def }}{=} \sum_{n=1}^{\infty} n^{-s} \varphi(n)^{-z} \\
& =\prod_{p}\left\{1+p^{-s}(p-1)^{-s}\left(1+p^{-s-z}+p^{-2 s-2 z}+\cdots\right)\right\} \\
& =\prod_{p}\left\{1-p^{-s-z}+p^{-s}(p-1)^{-z}\right\} \zeta(s+z) \\
& \stackrel{\text { def }}{=} \Pi(s, z) \zeta(s+z)
\end{aligned}
$$

was used in [2], and the function $g$ was represented by

$$
g(\alpha)=\frac{1}{2 \pi i} \int_{1 / 2-i \infty}^{1 / 2+i \infty} \frac{\Pi(1-z, z)}{z(1-z)} \alpha^{z} d z, \quad 0 \leqq \alpha \leqq 1
$$

The formula is valid at the end points by uniform convergence of the integral.

We delete the even integers and write

$$
\begin{aligned}
F_{0}(s, z) & =\sum_{\substack{n=1 \\
n \text { odd }}}^{\infty} n^{-s} \varphi(n)^{-z} \\
& =\Pi(s, z) \zeta(s+z)\left\{\frac{1-2^{-s-z}}{1-2^{-s-z}+2^{-s}}\right\} .
\end{aligned}
$$

The functions $F(s, z)$ and $F_{0}(s, z)$ have the same singularities in the region

$$
\{(s, z) \in \boldsymbol{C} \times \boldsymbol{C}: \operatorname{Re} s+z>0\}
$$

because any singularity of the new factor $\left(1-2^{-s-z}\right) /\left(1-2^{-s-z}+2^{-s}\right)$ is cancelled by a zero of $\Pi(s, z)$, and the new factor has no zeros in this region.

It now follows, mutatis mutandis, that

$$
\begin{aligned}
g_{0}(\alpha) & \stackrel{\text { def }}{=} \lim _{z \rightarrow \infty} \frac{1}{x} \#\{n \leqq x: n \text { odd, } \varphi(n) \leqq \alpha x\} \\
& =\frac{1}{2 \pi i} \int_{1 / 2-i \infty}^{1 / 2+i \infty} \frac{\Pi(1-z, z)}{z(1-z)} \alpha^{z}\left(1+2^{z}\right)^{-1} d z \\
& =\frac{1}{2 \pi i} \int_{1 / 2-i \infty}^{1 / 2+i \infty} \frac{\Pi(1-z, z)}{z(1-z)}\left\{\left(\frac{\alpha}{2}\right)^{z}-\left(\frac{\alpha}{4}\right)^{z}+\left(\frac{\alpha}{8}\right)^{z}-\cdots\right\} d z \\
& =g(\alpha / 2)-g(\alpha / 4)+g(\alpha / 8)-\cdots .
\end{aligned}
$$

If we note that $g_{0}(1)=1 / 2$ and sum the series $\zeta / 4-\zeta / 8+\zeta / 16-\cdots$ we obtain the lemma.

Now $g$ is concave and $g(\varepsilon) \sim \zeta \varepsilon$ as $\varepsilon \rightarrow 0$. Thus the series in the formula for $g(1 / 2)$ is alternating with terms decreasing to zero, indeed at a geometric rate. To further exploit our formula we must first estimate $D_{\varphi}(t)$ for $t$ near 0 .

Lemma 4. $D_{\varphi}(t)<12 t^{3}, 0<t<1$.
Proof. By Chebychev's inequality

$$
t^{-3} \sharp\left\{n \leqq x: \frac{\varphi(n)}{n} \leqq t\right\}=t^{-3} \sum_{\substack{n \in x \\ n \mid \varphi(n) \geq 1 / t}} 1 \leqq \sum_{n \leqq x}\left(\frac{n}{\varphi(n)}\right)^{3},
$$

and we estimate the last sum by writing

$$
(n / \varphi(n))^{3}=(1 * \beta)(n),
$$

where $*$ denotes multiplicative convolution and $\beta$ is a nonnegative multiplicative function satisfying $\beta(p)=\left(p^{3}-(p-1)^{3}\right) /(p-1)^{3}, \beta\left(p^{\alpha}\right)=0$ for all primes $p$ and all exponents $\alpha \geqq 2$.

Thus

$$
\begin{aligned}
& \sum_{n \leq x}\left(\frac{n}{\varphi(n)}\right)^{3}=\sum_{n \leq x}\left[\frac{x}{n}\right] \beta(n) \\
& \quad \leqq x \sum_{n=1}^{\infty} \frac{\beta(n)}{n}=x \prod_{p}\left(1+\frac{\beta(p)}{p}\right) \\
& \quad=x \prod_{p}\left\{1+\frac{1}{p} \frac{p^{3}-(p-1)^{3}}{(p-1)^{3}}\right\} \stackrel{\text { def }}{=} \gamma x .
\end{aligned}
$$

Now

$$
\begin{aligned}
\gamma & =\zeta(2)^{3} \prod_{p}\left\{1+\frac{3 p^{2}-3 p+1}{p(p-1)^{3}}\right\}\left\{1-\frac{1}{p^{2}}\right\}^{3} \\
& =\zeta(2)^{3} \prod_{p}\left\{1+\frac{6 p^{4}+4 p^{3}-3 p^{2}-p+1}{p^{7}}\right\} .
\end{aligned}
$$

It is easy to check that for all $p \geqq 3$

$$
6 p^{4}+4 p^{3}-3 p^{2}-p+1<7 p^{4} .
$$

We have

$$
\gamma \leqq \zeta(2)^{3}\left(1+\frac{115}{128}\right)\left\{\left(1+\frac{7}{3^{3}}\right)\left(1+\frac{7}{5^{3}}\right)\left(1+\frac{7}{7^{3}}\right)\right\} \exp \left\{\sum_{p \leqq 11} 7 p^{-3}\right\},
$$

and

$$
7 \sum_{p \geq 11} p^{-3}<7 \int_{10}^{\infty} t^{-3} d t=.035 .
$$

Thus $\gamma \leqq 12$, and $D_{\varphi}(t)$ satisfies the claimed bound.
We combine the last two lemmas with numerical data of Charles R. Wall [10] on the density function $D_{\varphi}$ to obtain upper and lower estimates for $g(1 / 2)$.

Lemma 5.

$$
\frac{1}{2}+\frac{\zeta}{6}-.00154<g(1 / 2)<\frac{1}{2}+\frac{\zeta}{6}-.00075 .
$$

Proof. The alternating series representation of $g(1 / 2)$ leads to the inequalities

$$
\begin{aligned}
\frac{1}{2}+ & \frac{\zeta}{6}-\left\{\left(\frac{\zeta}{4}-g\left(\frac{1}{4}\right)\right)-\left(\frac{\zeta}{8}-g\left(\frac{1}{8}\right)\right)+\left(\frac{\zeta}{16}-g\left(\frac{1}{16}\right)\right)\right\} \\
& \leqq g(1 / 2) \leqq \frac{1}{2}+\frac{\zeta}{6}-\left\{\left(\frac{\zeta}{4}-g\left(\frac{1}{4}\right)\right)-\left(\frac{\zeta}{8}-g\left(\frac{1}{8}\right)\right)\right\} .
\end{aligned}
$$

The differential equation (0) has the solution

$$
\begin{equation*}
u^{-1} g(u)=\zeta-\int_{0}^{u} D_{\varphi}(t) t^{-2} d t \tag{5}
\end{equation*}
$$

The constant is evaluated here by noting that $g^{\prime}(0)=\zeta$. The integral converges at zero by the preceding lemma. Thus we have

$$
2^{-k} \zeta-g\left(2^{-k}\right)=2^{-k} \int_{0}^{2^{-k}} D_{\varphi}(t) t^{-2} d t .
$$

It follows that

$$
\begin{aligned}
\left(\frac{\zeta}{4}\right. & \left.-g\left(\frac{1}{4}\right)\right)-\left(\frac{\zeta}{8}-g\left(\frac{1}{8}\right)\right)+\left(\frac{\zeta}{16}-g\left(\frac{1}{16}\right)\right) \\
& =\frac{1}{4} \int_{1 / 8}^{1 / 4} D_{\varphi}(t) \frac{d t}{t^{2}}+\frac{1}{8} \int_{1 / 18}^{1 / 8} D_{\varphi}(t) \frac{d t}{t^{2}}+\frac{3}{16} \int_{0}^{1 / 16} D_{\varphi}(t) \frac{d t}{t^{2}} .
\end{aligned}
$$

We estimate the three integrals from above, using the bound of the preceding lemma for $0 \leqq t \leqq .007$ and the upper bounds of Wall for $.007<t \leqq .25$. We obtain the upper bound . 00154 .

Similar treatment of

$$
\left(\frac{\zeta}{4}-g\left(\frac{1}{4}\right)\right)-\left(\frac{\zeta}{8}-g\left(\frac{1}{8}\right)\right)
$$

leads to the lower bound .00075 .
Lemma 6. (Main formula.)

$$
2 D_{\varphi}(1 / 2)-1+\zeta / 6+2 R=\int_{u_{0}}^{1 / 2} t^{-1} d D_{\varphi}(t),
$$

where $.00075<R<.00154$.
Proof. We have by (5)

$$
\frac{g\left(u_{0}\right)}{u_{0}}-\frac{g(1 / 2)}{1 / 2}=\int_{u_{0}}^{1 / 2} D_{\varphi}(t) t^{-2} d t .
$$

From (1) and the fact that $h^{\prime}\left(u_{0}\right)=0$ we get $g^{\prime}\left(u_{0}\right)=\zeta / 2$. Combining this with (0) we obtain

$$
g\left(u_{n}\right)=u_{0} \zeta / 2+D_{\varphi}\left(u_{0}\right) .
$$

This expression, Lemma 5, and the preceding integral yield

$$
\frac{D_{\varphi}\left(u_{0}\right)}{u_{0}}-1+\frac{\zeta}{6}+2 R=\int_{u_{0}}^{1 / 2} D_{\varphi}(t) t^{-2} d t .
$$

Integrating by parts we get the desired expression.
Theorem 4. $u_{0}>.473$ and $h_{0}<.324$.
Proof. Starting from Lemma 6, we write

$$
\begin{aligned}
& 2 D_{\varphi}\left(\frac{1}{2}\right)-1+\frac{\zeta}{6}+2 R=\left\{\int_{.475}^{.5}+\int_{u_{0}}^{.475}\right\} t^{-1} d D_{\varphi}(t) \\
& \quad \geqq \\
& \quad \frac{1}{.5}\left\{D_{\varphi}(.5)-D_{\varphi}(.499)\right\}+\frac{1}{.499}\left\{D_{\varphi}(.499)-D_{\varphi}(.498)\right\} \\
& \quad+\cdots+\frac{1}{.476}\left\{D_{\varphi}(.476)-D_{\varphi}(.475)\right\}+\frac{1}{.475}\left\{D_{\varphi}(.475)-D_{\varphi}\left(u_{o}\right)\right\},
\end{aligned}
$$

Note that this inequality is valid regardless of whether $u_{0} \leqq .475$ or not.

We rearrange terms, isolating $D_{\varphi}\left(u_{0}\right)$ :

$$
\begin{aligned}
\frac{D_{\varphi}\left(u_{0}\right)}{.475} \geqq & 1-\frac{\zeta}{6}-2 R+\left(\frac{1}{.499}-\frac{1}{.5}\right) D_{\varphi}(.499) \\
& +\cdots+\left(\frac{1}{.475}-\frac{1}{.476}\right) D_{\varphi}(.475) .
\end{aligned}
$$

If we use the upper estimate for $R$ and the lower estimates of [10] for $D_{\varphi}(.475), \cdots, D_{\varphi}(.499)$, we find that $D_{\varphi}\left(u_{0}\right)>.3380$.

The stated inequalities follow at once from this bound. First, we have from [10] that $D_{\varphi}(.473)<.3362$, and thus $u_{0}>.473$. Next, it follows from Equations (0) and (1) that $h_{0}=1-2 D_{\varphi}\left(u_{0}\right)$. Thus, $h_{0}<.324$.

We also have bounds for $u_{0}$ and $h_{0}$ in the opposite directions.
Theorem 5. $u_{0}<.475$ and $h_{0}>.321$.
Proof. Using Lemma 6 again, we write

$$
2 D_{\varphi}\left(\frac{1}{2}\right)-1+\frac{\zeta}{6}+2 R=\left\{\int_{.775}^{.5}+\int_{u_{0}}^{.475}\right) t^{-1} d D_{\varphi}(t) .
$$

This time we express the first integral as an upper Riemann-Stieltjes sum and sum by parts to obtain

$$
\begin{aligned}
\int_{.475}^{.5} t^{-1} d D_{\varphi}(t) \leqq & \frac{D_{\varphi}(.5)}{.499}+\left(\frac{1}{.498}-\frac{1}{.499}\right) D_{\varphi}(.499) \\
& +\cdots+\left(\frac{1}{.475}-\frac{1}{.476}\right) D_{\varphi}(.476)-\frac{D_{\varphi}(.475)}{.475}
\end{aligned}
$$

Thus

$$
\int_{u_{0}}^{.475} t^{-1} d D_{\varphi}(t) \geqq \frac{D_{\varphi}(.475)}{.475}-I,
$$

where

$$
I=1-\frac{\zeta}{6}-2 R+\left(\frac{1}{.499}-\frac{1}{.5}\right) D_{\varphi}(.5)+\cdots+\left(\frac{1}{.475}-\frac{1}{.476}\right) D_{\varphi}(.476) .
$$

We estimate $I$ from above by using the upper bounds for $D_{\varphi}(.476), \cdots, D_{\varphi}(.500)$ from [10] and the lower bound for $R$ from Lemma 6. We obtain the inequality

$$
\begin{equation*}
\int_{x_{0}}^{.475} t^{-1} d D_{\varphi}(t) \geqq \frac{D_{\varphi}(.475)}{.475}-.7145, \tag{6}
\end{equation*}
$$

from which both assertions of the theorem will follow.
The bound $D_{\varphi}(.475) \geqq .33969$ from [10] implies that

$$
\int_{u_{0}}^{.475} t^{-1} d D_{\varphi}(t)>.0006>0
$$

and hence $u_{0}<.475$.
Next, since $u_{0}>.473$, we obtain from (6)

$$
\frac{1}{.473}\left\{D_{\varphi}(.475)-D_{\varphi}\left(u_{0}\right)\right\} \geqq \frac{D_{\varphi}(.475)}{.475}-.7145 .
$$

This inequality and the bound $D_{\varphi}(.475)<.34166$ from [10] yield $D_{\varphi}\left(u_{0}\right)<.3394$. Thus, we finally obtain $h_{0}=1-2 D_{\varphi}\left(u_{0}\right)>.321$.
6. Lower estimates for $F$. The sequence $F(n)$ tends to infinity with $n$, since

$$
F(n) / n \sim h(\varphi(n) / n) \geqq h_{0}>0 .
$$

In this section we are going to establish
Theorem 6. As $x \rightarrow \infty$,

$$
\min _{n>x} F(n) \sim h_{0} x .
$$

This estimate follows easily from the following
Lemma 7. Let $\alpha \in(0,1)$ and let $\varepsilon>0$ be given. Then there exists an $X$ (depending on $\varepsilon$ and $\alpha$ ) such that for each $x \geqq X$, the interval $(x, x+\varepsilon x]$ contains an integer $j$ with $|\varphi(j) / j-\alpha|<\varepsilon$.

Proof. The argument proceeds in two steps. First we obtain some integer $j_{0}$ (not necessarily in ( $\left.x, x+\varepsilon x\right]$ ) composed of at least two distinct prime factors, for which $\left|\varphi\left(j_{0}\right) / j_{0}-\alpha\right|<\varepsilon$. Then we show that a suitable multiple of $j_{0}$ lies in $(x, x+\varepsilon x]$ and satisfies the same $\varphi$ estimate.

Let $\alpha=\alpha_{0}$. Let $q_{1}$ be the smallest prime $p_{y}$ for which 1-$p_{v}^{-1}>\alpha_{0}$. Set $\alpha_{1}=\alpha_{0}\left(1-q_{1}^{-1}\right)^{-1}$ and $j_{1}=q_{1}$. Repeat the foregoing, choosing $q_{2}$ to be the smallest prime $p_{2}$ exceeding $q_{1}$ for which $1-p_{\downarrow}^{-1}>\alpha_{1}$. Let $j_{2}=q_{1} q_{2}$ and $\alpha_{2}=\alpha_{1}\left(1-q_{2}^{-1}\right)^{-1}$. If $1>\alpha_{2}>1-$ $\varepsilon /(\alpha+\varepsilon)$, we can stop here. Otherwise we continue until we obtain an integer $j_{r}=q_{1} q_{2} \cdots q_{r}, r=r(\alpha, \varepsilon)$, such that

$$
\alpha \leqq \varphi\left(j_{\tau}\right) / j_{r}<\alpha+\varepsilon .
$$

This is possible to achieve since $1-p_{\nu}^{-1} \rightarrow 1$ as $\nu \rightarrow \infty$ and $\Pi_{\vee=1}^{\infty}\left(1-p_{\nu}^{-1}\right)=0$.

Set $j_{\nu}=j^{*}$ and consider the sequence $\left\{j^{*} q_{1}^{a} q_{2}^{b}: a, b=0,1,2,3, \cdots\right\}$. Clearly

$$
\varphi\left(j^{*}\right) / j^{*}=\varphi\left(j^{*} q_{1}^{a} a_{2}^{b}\right) /\left(j^{*} q_{1}^{a} q_{2}^{b}\right) .
$$

It suffices to show that for each large $x$ the interval $(x, x+\varepsilon x]$ contains some $q_{1}^{a} q_{2}^{b}, a, b \geqq 0$.

It is well known that the sequence $\left\{q_{1}^{a} q_{2}^{b}: a, b \in \boldsymbol{Z}\right\}$ is dense in the positive reals for $q_{1}, q_{2}$ distinct primes. Choose $a>0$ and $-b<0$ such that $1<q_{1}^{a} q_{2}^{-b}<1+\varepsilon$. Given $x$, set

$$
\begin{aligned}
& s=\left[(\log x) /\left(\log q_{1} q_{2}\right)\right], \\
& t=\left[\left(\log q_{1} q_{2}\right) /\left(\log q_{1}^{a} q_{2}^{-b}\right)\right]+1,
\end{aligned}
$$

and $a_{k}=q_{1}^{s+k a} q_{2}^{s-k b},(0 \leqq k \leqq t)$.
We have

$$
a_{0}=\left(q_{1} q_{2}\right)^{s} \leqq x<\left(q_{1} q_{2}\right)^{s+1}<a_{t}
$$

and

$$
1<a_{k+1} / a_{k}=q_{1}^{a} q_{2}^{-b}<1+\varepsilon .
$$

Thus there exists some $k \in[1, t]$ such that $x<q_{1}^{3+k a} q_{2}^{s-k b}<x+\varepsilon x$.
Finally, we must insure that the exponent $s-k b \geqq 0$. This we do by noting that $a, b$, and $t$ depend only on $\varepsilon$ and are fixed, while $s \rightarrow \infty$ with $x$.

Lemma 8. Given $\varepsilon>0$ there exists an $X=X(\varepsilon)$ such that for each $x \geqq X$ the interval ( $x, x+\varepsilon x$ ] contains an integer $j$ with $h(\varphi(j) / j)<h_{0}+2 \varepsilon$.

Proof. Since $h$ is convex and differentiable we have

$$
\left|h^{\prime}(x)\right| \leqq \max \left\{\left|h^{\prime}(0)\right|,\left|h^{\prime}(1)\right|\right\}=\zeta, \quad 0 \leqq x \leqq 1 .
$$

The mean value theorem and Lemma 7 imply that there exists an integer $j$ in each far out interval $(x, x+\varepsilon x]$ such that

$$
\left|h(\phi(j) / j)-h_{0}\right| \leqq \zeta\left|\frac{\varphi(j)}{j}-u_{0}\right|<\zeta \varepsilon<2 \varepsilon .
$$

Proof of Theorem 6. On the one hand,

$$
\begin{aligned}
\min _{n>x} F(n) & =\min _{n>x}\left\{n h(\varphi(n) / n)+O\left(n e^{-\sqrt{\log n}}\right)\right\} \\
& \geqq x h_{0}-c x e^{-\sqrt{\log x}}=h_{0} x+o(x) .
\end{aligned}
$$

On the other hand, for given $\varepsilon>0$ and all sufficiently large $x$ there exists an integer $m$ such that

$$
x<m \leqq x+\varepsilon x, \quad h(\varphi(m) / m)<h_{0}+2 \varepsilon
$$

For this integer $m$ we have

$$
F(m)<\left(h_{0}+2 \varepsilon\right) m+c m e^{-\sqrt{\log m}},
$$

and hence

$$
\begin{aligned}
\min _{n>x} F(n) & \leqq F(m) \leqq\left(h_{0}+2 \varepsilon\right)(x+\varepsilon x)+2 c x e^{-\sqrt{\log x}} \\
& \leqq h_{0} x+o(x) .
\end{aligned}
$$

Let $\left\{m_{k}\right\}_{k=1}^{\infty}$ be the sequence of discontinuities of $x \mapsto \min _{n>\infty} F(n)$. (Set $m_{1}=2$.) We can deduce from Theorem 6 the following

Corollary 3. $\quad m_{k+1} / m_{k} \rightarrow 1$ as $k \rightarrow \infty$.
Proof. For $m_{k} \leqq x<m_{k+1}$ we have

$$
\min _{n>m_{k}} F(n)=\min _{n>x} F(n) .
$$

Thus $h_{0} m_{k} \sim h_{0} x$. Let $x \rightarrow m_{k+1}-$.
7. General arithmetic functions. We conclude by showing that rather general arithmetic functions ir possess an associated monotonicity measuring function $F=F_{\psi}$. Our argument is related to one occurring in [4]. It appears unlikely that there are general analogues of our numbered theorems in $\S \S 3-6$ which are valid without more specific arithmetic information.

It is convenient to estimate the two components of $F$ separately. Let

$$
\begin{aligned}
& F_{1}(n)=\sharp\{m<n: \psi(m) \geqq \psi(n)\}, \\
& F_{2}(n)=\sharp\{m>n: \psi(m) \leqq \psi(n)\} .
\end{aligned}
$$

In both cases we assume that $\psi$ is positive valued and that $\psi(n) / n$ has a distribution function $D_{\psi}$.

Theorem 7. Let ir be as above. Then, as $n \rightarrow \infty$,

$$
\begin{equation*}
F_{1}(n)=\psi(n) \int_{t=\psi(n) / n}^{\infty}\left\{1-D_{\psi}(t)\right\} t^{-2} d t+o(n) . \tag{7}
\end{equation*}
$$

Further, assume that there exist positive numbers $c$ and $\delta$ such that

$$
\begin{equation*}
\#\{m \in(x, 2 x]: \psi(m) / m<y\} \leqq c x y^{1+\jmath} \tag{8}
\end{equation*}
$$

holds for all $y \in(0,1)$ and all $x \geqq 1$. Then

$$
\begin{equation*}
F_{2}(n)=\psi \psi(n) \int_{t=0}^{\psi(n) / n} D_{\psi}(t) t^{-2} d t+o(n+\dot{\psi}(n)) . \tag{9}
\end{equation*}
$$

Remarks. A. It is a simple consequence of hypothesis (8) that there exist at most a finite number of integers $n$ for which $\psi(n)$ assumes any one value. Also, (8) implies that the integral in (9) converges at the origin.
B. For application to the Euler $\varphi$ function, the estimate

$$
\sum_{m=1}^{n}(m / \psi(m))^{2} \ll n
$$

(cf. [4]) guarantees that (8) holds with $\delta=1$. Condition (8) is vacuous for the sum of divisors function $\sigma$, since $\sigma(n) \geqq n$ for all $n \geqq 1$.
C. Can we replace the equal sign in (7) or in (9) by " $\sim$ " and drop the o-term? This is not generally permissible for (7) as one can see by the case in which $D_{\psi}(\alpha)=1$ for some finite $\alpha, \psi(n) / n \geqq \alpha$, and there exists at least one integer $m<n$ such that $\psi(m) \geqq \psi(n)$. The conjecture is also generally false for (9) as well, as we can see in the case where $D_{\varphi}(t)>0$ for all $t>0$. By Remark A there exists an infinite number of integers $n$ for which $F_{2}(n)=0$, and for these $n$ the asymptotic relation would fail.

Proof. We shall show that (9) holds. The proof of (7) is similar but simpler, and is omitted.

Proof. We introduce a partition of ( $n, \infty$ ). Let $\varepsilon>0, K \in \boldsymbol{Z}^{+}$ with $\varepsilon K>1$ and let $n^{\prime}=n+\psi(n)$. Write

$$
(n, \infty)=\bigcup_{i=1}^{K}\left(n+(i-1) \varepsilon n^{\prime}, n+i \varepsilon n^{\prime}\right] \cup\left(n+K \varepsilon n^{\prime}, \infty\right) .
$$

For the finite intervals we use the following estimates, which are valid for $1 \leqq x<y<\infty$ :

$$
\begin{aligned}
\#\{m & \in(x, y]: \psi(m) \leqq m \psi(n) / y\} \\
& \leqq \# \# \# \\
& \leqq \#\{m \in(x, y]: \psi(m) \leqq \psi(n)\} \\
& \leqq\{m \in(x, y]: \psi(m) \leqq m \psi(n) / x\},
\end{aligned}
$$

and hence

$$
(y-x) D_{\psi}(\psi(n) / y)+o(y) \leqq \# \leqq(y-x) D_{\psi}(\psi(n) / x)+o(y) .
$$

If we set

$$
\Sigma=\varepsilon n^{\prime} \sum_{i=1}^{K} D_{\psi}\left(\psi(n) /\left(n+i \varepsilon n^{\prime}\right)\right)
$$

and

$$
F_{2}(a, b)=\#\{m \in(a, a+b]: \psi(m) \leqq \psi(n)\},
$$

then we obtain

$$
\begin{aligned}
\Sigma+ & K o\left(K \varepsilon n^{\prime}\right) \leqq F_{2}\left(n, K \varepsilon n^{\prime}\right) \\
& \leqq \sum+\varepsilon n^{\prime} D_{\psi}\left(\psi^{\prime}(n) / n\right)-\varepsilon n^{\prime} D_{\psi}\left(\psi(\eta) /\left(n+K \varepsilon n^{\prime}\right)\right) \\
& +K o\left(K \varepsilon n^{\prime}\right) .
\end{aligned}
$$

Now $\Sigma$ is an approximating sum for the Riemann integral

$$
\begin{aligned}
I & =\varepsilon n^{\prime} \int_{t=0}^{K} D_{\psi}\left(\psi(n) /\left(n+t \varepsilon n^{\prime}\right)\right) d t \\
& =\psi(n) \int_{s=\psi(n) /\left(n+K t n^{\prime}\right)}^{\psi(n) / n} D_{\dot{\psi}}(s) s^{-2} d s
\end{aligned}
$$

and since the integrand in the first expression is monotone, we get $|I-\Sigma|<\varepsilon n^{\prime}$. The hypotheses on $\psi(n) / n$ imply that

$$
D_{\psi}(y) \leqq C y^{1+\delta}, \quad 0<y<1 .
$$

Thus

$$
\int_{0}^{\psi(n) /\left(n+K E n^{\prime}\right)} D_{\psi}(t) t^{-2} d t \leqq \frac{C}{\delta}\left(\frac{\psi(n)}{n+K \varepsilon n^{\prime}}\right)^{\delta} \leqq \frac{C}{\delta}(K \varepsilon)^{-\delta} .
$$

Combining these estimates we find that

$$
\begin{aligned}
F_{2}\left(n, K \varepsilon n^{\prime}\right)= & \psi(n) \int_{0}^{\psi(n) / n} D_{\psi}(t) t^{-2} d t \\
& +O\left(\varepsilon n^{\prime}\right)+K o\left(K \varepsilon n^{\prime}\right)+O\left((K \varepsilon)^{-\delta} n^{\prime}\right) .
\end{aligned}
$$

Now we treat the unbounded interval. For each $x \geqq 1$ we have

$$
\begin{aligned}
F_{2}(x, x) & \leqq \#\{m \in(x, 2 x]: \psi(m) / m \leqq \psi(n) / x\} \\
& \leqq C x(\psi(n) / x)^{1+\delta} .
\end{aligned}
$$

Thus

$$
\begin{aligned}
F_{2}\left(n+K \varepsilon n^{\prime}, \infty\right) & \leqq C \psi(n)^{1+\jmath}\left(n+K \varepsilon n^{\prime}\right)^{-\delta}\left(1+2^{-\delta}+4^{-\delta}+\cdots\right) \\
& \ll \psi(n)(K \varepsilon)^{-\delta} .
\end{aligned}
$$

It follows that

$$
\begin{aligned}
F_{2}(n)= & \psi(n) \int_{0}^{\psi(n) / n} D_{\psi}(t) t^{-2} d t \\
& +O\left(\varepsilon n^{\prime}\right)+K^{2} \varepsilon o\left(n^{\prime}\right)+O\left((K \varepsilon)^{-\delta} n^{\prime}\right) .
\end{aligned}
$$

If we first choose $\varepsilon$ small and then $K$ so large that $(K \varepsilon)^{-\delta}$ is small, we obtain the desired asymptotic.
